Revised 31 August 2007

Communicated by G. Dal Maso

This paper addresses a three-dimensional model for isothermal stress-induced transformation in shape-memory polycrystalline materials. We treat the problem within the framework of the energetic formulation of rate-independent processes and investigate existence and continuous dependence issues at both the constitutive relation and quasi-static evolution level. Moreover, we focus on time and space approximation as well as on regularization and parameter asymptotics.

Keywords: Shape-memory materials; rate-independent evolution; existence; time and space discretization; Γ -convergence; asymptotics; error.

AMS Subject Classification: 74C05, 49J40

1. Introduction

Shape-memory materials are metallic alloys showing some surprising thermo-mechanical behavior: severely deformed specimens with residual strain up to 15% regain their original shape after a thermal cycle (*shape-memory effect*). Moreover, the same materials are *super-elastic* (also called *pseudo-elastic*), namely, they recover comparably large deformations during mechanical loading-unloading cycles at prescribed temperatures (see, among others, Refs. 1, 6, 21, 23, 25, 46 and 75). These features, which are not present (at least to this extent) in materials traditionally used in engineering, are at the basis of the innovative and commercially valuable applications of shape-memory materials. Namely, shape-memory technologies are nowadays exploited in a variety of different applicative contexts ranging from sensors and actuators (even microscopical), to robotics, to clamping and fixation devices, to space applications (grippers, positioners), to damping devices (shock absorption).⁵⁶ The largest commercial success of shape-memory materials is however related to biomedical applications. The combination of good bio-compatibility and interesting material properties creates unique materials for medical tools and devices. Nowadays, shape-memory materials are successfully used in orthodontics (archwires), orthopedics (bone anchors, intramedullary fixations, bone staples), medical instruments, minimal invasive surgery technology (catheters, endoguidewires, grippers, cutters), drug delivery systems, and both intravascular (cardiovascular stenting, bronchial biliary, aortic aneurysm, carotid stenosis) and extravascular scaffolding. In particular, shape-memory stents are the key tool in order to implement a variety of quite successful non-invasive surgical techniques.^{15,54,55}

The present analysis is concerned with the quasi-static evolution of shape-memory materials in the small-strain regime. In particular, we shall study a macroscopic phenomenological model for shape-memory polycrystalline materials undergoing stress-induced transformations that was originally proposed by Souza *et al.*⁵³ and later addressed and extended by Auricchio & Petrini,^{4,5} and Auricchio *et al.*⁷ Our aim is to focus on the isothermal situation at suitably high temperatures in order to capture the super-elastic material behavior. The understanding and the efficient description of the super-elastic regime is clearly of a great applicative interest. In particular, most of the biomedical applications enlisted above are based on super-elastic deployment *in situ* and/or super-elastic kink resistance of shape-memory materials.

Let us briefly recall here the basic features of the proposed model, the interested reader is of course referred to the above-mentioned contributions for all the necessary modeling details and motivations as well as for some computations and validation. The formal character of this introduction is for the purpose of a general overview on the model and our results. In particular, (most of) the mathematical details are omitted here and will be provided in the forthcoming sections.

Moving into the frame of Generalized Standard Materials (see Ref. 29) and within the small-strain regime, we additively decompose the linearized deformation

$\varepsilon = (\varepsilon_{ij}) = (u_{i,j} + u_{j,i})/2$, (u being the displacement from a fixed reference configuration $\Omega \subset \mathbb{R}^3$) into the elastic part ε_{el} and the inelastic (or transformation) part z as

$$\varepsilon = \varepsilon_{el} + z. \tag{1.1}$$

At the microscopic level the super-elastic effect is interpreted as the result of a structural phase transition between different configurations of the material lattices, namely the *parent phase* (austenite and twinned martensite) and its shared counterpart termed *product phase* (detwinned martensite). In particular, the internal variable z is assumed to be descriptive of the mechanical (tensorial) effect of the detwinning observed in the material.

Denoting by $W(\varepsilon, z)$ the stored energy density of the system, the evolution of the material will be described by the following classical relations:

$$\sigma = \partial W / \partial \varepsilon, \tag{1.2}$$

$$-\xi = \partial W / \partial z, \tag{1.3}$$

$$\dot{z} = \nabla D^*(\xi). \tag{1.4}$$

Here, ξ denotes the thermodynamic force associated with z and (1.4) is the flow rule for z where D^* stands for the Legendre conjugate of the dissipation density D (see below).

The material constitutive relations (1.2)–(1.4) may be conveniently rewritten in the following equivalent subdifferential formulation:

$$\begin{pmatrix} 0 \\ \partial D(\dot{z}) \end{pmatrix} + \begin{pmatrix} \partial_\varepsilon W(\varepsilon, z) \\ \partial_z W(\varepsilon, z) \end{pmatrix} \ni \begin{pmatrix} \sigma \\ 0 \end{pmatrix}, \tag{1.5}$$

where D stands for the dissipation density and the symbol ∂ denotes subdifferentials in the sense of Convex Analysis (see below).

The evolution problem (1.5) may be set within the frame of energetic formulations of rate-independent processes recently proposed by Mielke *et al.*^{28,42,44} The notion of energetic solution (discussed in some detail in the forthcoming Sec. 2) is based on equivalently recasting the subdifferential problem (1.5) as the coupling of a global stability condition and an energy conservation relation. In particular, the subdifferential relation (1.5) is rewritten as

$$\text{(stability)} \quad (\varepsilon(t), z(t)) \in \underset{(\bar{\varepsilon}, \bar{z})}{\text{Arg Min}}(W(\bar{\varepsilon}, \bar{z}) - \sigma(t) : \bar{\varepsilon} + D(\bar{z} - z(t))), \tag{1.6}$$

$$\begin{aligned} \text{(energyequality)} \quad & W(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t) + \text{Diss}_D(z, [0, t]) \\ & = W(\varepsilon_0, z_0) - \sigma(0) : \varepsilon_0 - \int_0^t \dot{\sigma}(s) : \varepsilon(s) \, ds, \end{aligned} \tag{1.7}$$

for all $t \geq 0$. Here, we assume to be given some suitable initial data (ε_0, z_0) and the stress $t \mapsto \sigma(t)$ and denote the total dissipation of the system on $[0, t]$ as

$$\begin{aligned} & \text{Diss}_D(z, [0, t]) \\ & := \sup \left\{ \sum_{i=1}^N D(z(t_i) - z(t_{i-1})) : \{0 = t_0 < t_1 < \dots < t_{N-1} < t_N = t\} \right\}, \end{aligned} \tag{1.8}$$

where the supremum is taken with respect to all finite partitions of $[0, t]$. Energetic formulations were originally developed for shape-memory alloys in Mielke & Theil and Mielke *et al.*,^{42–44} and have shown to be extremely well-suited for a variety of different rate-independent situations. In particular, they have been successfully considered in connection with elasto-plasticity,^{12,13,33–36} damage,³⁹ brittle fractures,¹⁴ delamination,²⁸ ferro-electricity,⁴⁵ shape-memory alloys,^{38,42,44} and vortex pinning in superconductors.⁵² The reader is referred to Ref. 37 for a comprehensive survey of the mathematical theory.

Let us now introduce the precise form of W we will deal with. Namely, we choose

$$W(\varepsilon, z) = \frac{1}{2}\mathbb{C}(\varepsilon - z) : (\varepsilon - z) + c_1|z| + c_2|z|^2 + I(z) + \frac{\nu}{2}|\nabla z|^2. \quad (1.9)$$

Here, \mathbb{C} is the elasticity tensor and the positive parameters c_1 and c_2 are given. Indeed, in Ref. 53 the constant c_1 is assumed to depend explicitly on the temperature of the specimen while here temperature effects are neglected. On the other hand, c_2 measures the occurrence of some hardening phenomenon with respect to the internal variable z . The function I is the indicator of a fixed closed ball of radius $c_3 > 0$. In particular, c_3 represents the maximum modulus of transformation strain that can be obtained by alignment (detwinning) of the martensitic variants. Finally, the positive coefficient ν is expected to measure some nonlocal interaction effect for the internal variable z and ∇z stands for the usual gradient with respect to the spatial variables. Indeed, gradients of inelastic strains have already been considered in the frame of shape-memory materials in Ref. 20 and the reader is referred also to Refs. 2, 22, 26, 38, 50 and 51 for examples and discussions on nonlocal energy contributions of z .

The proposed model is capable of describing the main features of the super-elastic evolution of shape-memory materials. In particular, the internal variable tensorial character of the model allows one for taking into account the so-called *single-variant martensite reorientation* phenomenon. Namely, also in the case the material is fully transformed into product phase (i.e. $|z| = c_3$), inelastic strain changes can still be experienced due to variant reorientation ($\dot{z} \neq 0$). This fact is experimentally observed and turns out to be crucial with respect to applications. Moreover, whenever not restricted to the isothermal situation, the model turns out to be thermodynamically consistent in the sense that the Second Law of Thermodynamics is satisfied in the form of the Clausius–Duhem inequality.

As for the full quasi-static evolution of the material we shall couple the constitutive relation (1.5) with the equilibrium equation

$$\operatorname{div} \sigma + f = 0 \quad \text{in } \Omega, \quad (1.10)$$

where f is a given body force, suitably complemented with some prescribed boundary displacement and boundary traction in distinguished parts of the boundary of Ω .

The first issue of this paper is that of adapting the above referred abstract theory for energetic formulations to the quasi-static evolution problem and obtain that (Theorem 6.1)

(existence) the quasi-static problem admits at least one energetic solution $t \mapsto (u(t), z(t))$.

We shall be concerned with some specific regularization of the original quasi-static model. Namely, some smooth variant of the potential W above turns out to be better suited for the sake of numerical considerations. In particular, we will consider a regularized version of the model by posing

$$W_{\rho,\nu}(\varepsilon, z) = \frac{1}{2}\mathbb{C}(\varepsilon - z) : (\varepsilon - z) + F_\rho(z) + \frac{\nu}{2}|\nabla z|^2, \quad (1.11)$$

where $\nu \geq 0$ and F_ρ is some regularization of $F_0 : z \mapsto c_1|z| + c_2|z|^2 + I(z)$ obtained by penalization and smoothing and depending on the regularization parameter $\rho \geq 0$. This regularization is exactly the starting point of Refs. 4, 5 and has been exploited in Ref. 7 as well (in all these papers $\nu = 0$ though).

A second focus of the present contribution is on unique solvability of the regularized model. In particular, we check that

(uniqueness for $\rho > 0$) for $\rho > 0$, the quasi-static problem has a unique solution.

This uniqueness result was proved in an abstract frame in Refs. 42, 43 and is here reconsidered in the specific situation of the regularized version of the quasi-static problem.

A quite natural approach to rate-independent evolution problems relies on implicit time-discretization. This perspective is investigated here and complemented with some space approximation technique. In particular, the main novelty of this paper is the convergence analysis for the discretized-regularized model. Namely, we consider the (possibly joint) limits with respect to the time-steps τ of time partitions (here considered to be constant for simplicity), the space mesh size h (conforming finite elements are exploited), and the regularization parameter ρ . In particular, denoting by $(u, z)_{\rho,\tau,h}$ the unique solution to the spacetime discrete problem with the parameter-choice $\rho \geq 0$ (time-interpolant, piecewise constant on the time-partition) and by $(u, z)_\rho$ the time-continuous solution to the problem for $\rho \geq 0$, we prove the following (Theorem 7.4)

(convergence for $\rho > 0$) for $\rho > 0$, $(u, z)_{\rho,\tau,h}$ converges to $(u, z)_\rho$ as $(\tau, h) \rightarrow (0, 0)$,
 (full convergence) up to a subsequence, $(u, z)_{\rho,\tau,h} \rightarrow (u, z)_0$ as $(\rho, \tau, h) \rightarrow (0, 0, 0)$.

Of course the topologies under which the latter convergences hold true will be specified in the forthcoming sections.

Indeed much more is true and we are in the position of giving a full picture of convergences for the model subsequently. Moving from Sec. 2 where the mathematical formulation of the problem is presented, we shall organize our results by successively increasing complexity. Section 3 addresses the analysis of the constitutive relation problem (1.5), namely the zero-dimensional problem. In particular, we prove well-posedness and convergence of time-discrete approximations. Then, the three-dimensional minimum problem arising from time-discretization is addressed

in Sec. 4 where we also investigate well-posedness and convergence of space approximations along with suitable error bounds. Some *a priori* bounds and a preliminary convergence result for the incremental solutions to the problem in case the time-partition is fixed are discussed in Sec. 5. Finally, the three-dimensional quasi-static evolution problem is tackled in Sec. 6 where we provide the existence, uniqueness, and convergence results for the space-time discrete solutions. Finally, Sec. 7 deals with convergence issues with respect to parameters and discretizations in full generality.

2. Mathematical Formulation

Tensors. We will denote by $\mathbb{R}_{\text{sym}}^{3 \times 3}$ the space of symmetric 3×3 tensors endowed with the natural scalar product $a : b := \text{tr}(ab) = a_{ij}b_{ij}$ (summation convention) and the corresponding norm $|a|^2 := a : a$ for all $a, b \in \mathbb{R}_{\text{sym}}^{3 \times 3}$. The space $\mathbb{R}_{\text{sym}}^{3 \times 3}$ is orthogonally decomposed as $\mathbb{R}_{\text{sym}}^{3 \times 3} = \mathbb{R}_{\text{dev}}^{3 \times 3} \oplus \mathbb{R}1_2$, where $\mathbb{R}1_2$ is the subspace spanned by the identity 2-tensor 1_2 and $\mathbb{R}_{\text{dev}}^{3 \times 3}$ is the subspace of deviatoric symmetric 3×3 tensors. In particular, for all $a \in \mathbb{R}_{\text{sym}}^{3 \times 3}$, we have that $a = a_{\text{dev}} + \text{tr}(a)1_2/3$. For all $u \in H_{\text{loc}}^1(\mathbb{R}^3; \mathbb{R}^3)$ we let $\varepsilon(u) \in L_{\text{loc}}^2(\mathbb{R}^3; \mathbb{R}_{\text{sym}}^{3 \times 3})$ denote the standard symmetric gradient.

Reference configuration. We shall assume Ω to be a non-empty, bounded, and connected open set in \mathbb{R}^3 with a Lipschitz continuous boundary. The space dimension 3 plays essentially no role throughout the analysis and we would be in the position of reformulating our results in \mathbb{R}^d with no particular intricacy. We assume that the boundary $\partial\Omega$ is partitioned in two disjoint open sets Γ_{tr} and Γ_{Dir} with $\partial\Gamma_{\text{tr}} = \partial\Gamma_{\text{Dir}}$ (in $\partial\Omega$). We ask Γ_{Dir} to be such that there exists a positive constant c_0 depending on Γ_{Dir} and Ω such that the Korn inequality

$$c_0 \|u\|_{H^1(\Omega; \mathbb{R}^3)}^2 \leq \|u\|_{L^2(\Gamma_{\text{Dir}}; \mathbb{R}^3)}^2 + \|\varepsilon(u)\|_{L^2(\Omega; \mathbb{R}_{\text{sym}}^{3 \times 3})}^2, \quad (2.1)$$

holds true for all $u \in H^1(\Omega; \mathbb{R}^3)$. It would indeed suffice to impose Γ_{Dir} to have a positive surface measure (see, e.g., Theorem 3.1 of Ref. 16).

Prescribed boundary displacement. We will prescribe some nonhomogeneous Dirichlet boundary conditions on Γ_{Dir} . To this end, we will assign $u^{\text{Dir}} \in C^1([0, T]; H^{1/2}(\Gamma_{\text{Dir}}, \mathbb{R}^3))$ or, equivalently, $u^{\text{Dir}} \in C^1([0, T]; H^1(\Omega, \mathbb{R}^3))$ whose trace on Γ_{Dir} is the prescribed boundary value for the displacement u . On Γ_{tr} some time-dependent traction will be prescribed instead.

Elastic energy. Let \mathbb{C} be the elasticity tensor. The latter is regarded as a symmetric positive definite linear map $\mathbb{C} : \mathbb{R}_{\text{sym}}^{3 \times 3} \rightarrow \mathbb{R}_{\text{sym}}^{3 \times 3}$. We shall assume that the orthogonal subspaces $\mathbb{R}_{\text{dev}}^{3 \times 3}$ and $\mathbb{R}1_2$ are invariant under \mathbb{C} . This amounts to saying that indeed

$$\mathbb{C}a = \mathbb{C}_{\text{dev}}a_{\text{dev}} + \kappa \text{tr}(a)1_2,$$

for a given $\mathbb{C}_{\text{dev}} : \mathbb{R}_{\text{dev}}^{3 \times 3} \rightarrow \mathbb{R}_{\text{dev}}^{3 \times 3}$ and a constant κ , and all $a \in \mathbb{R}_{\text{sym}}^{3 \times 3}$. The case of isotropic materials is given by $\mathbb{C}_{\text{dev}} = 2G(1_4 - 1_2 \otimes 1_2/3)$ and G and κ are respectively the shear and the bulk moduli. The latter decomposition is not exploited in our analysis but it is clearly suggested by the mechanical application.

We will make use of the stored elastic energy functional $\mathcal{C} : L^2(\Omega; \mathbb{R}_{\text{sym}}^{3 \times 3}) \rightarrow [0, +\infty)$ defined as

$$\mathcal{C}(a) := \frac{1}{2} \int_{\Omega} \mathbb{C}(a) : adx.$$

Inelastic energy. As for the stored inelastic (or transformation) energy we shall prescribe the function $F : \mathbb{R}_{\text{dev}}^{3 \times 3} \rightarrow [0, +\infty]$ as

$$F(a) = c_1|a| + c_2|a|^2 + I(a),$$

where $I : \mathbb{R}_{\text{dev}}^{3 \times 3} \rightarrow [0, +\infty]$ is the indicator function of the ball $\{a \in \mathbb{R}_{\text{dev}}^{3 \times 3} : |a| \leq c_3\}$ and the positive constants c_1, c_2 , and c_3 are given. Moreover, the stored inelastic energy functional is defined as $\mathcal{F} : L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \rightarrow [0, +\infty]$ as

$$\mathcal{F}(a) := \begin{cases} \int_{\Omega} F(a)dx & \text{if } F(a) \in L^1(\Omega) \\ +\infty & \text{otherwise.} \end{cases}$$

The well-posedness and time discretization issues discussed here do not rely on the particular form of F and could be adapted to any uniformly convex, proper and lower semicontinuous function. We however prefer to stick to the actual modeling choice for the sake of clarity. In a forthcoming paper we will address some suitable regularization of F . Indeed, we introduce an approximation parameter $\rho \geq 0$ and some functions

$$F_{\rho} \in C^{2,1}(\mathbb{R}_{\text{dev}}^{3 \times 3}) \text{ with } \nabla^2 F_{\rho} \text{ bounded, } \nabla^2 F_{\rho} \geq c_2 1_4 \text{ and } F_{\rho}(0) = 0, \quad (2.2)$$

and define $F_0 := F$. An example in the direction of (2.2) is

$$F_{\rho}(a) := c_1(\sqrt{\rho^2 + |a|^2} - \rho) + c_2|a|^2 + \varphi(|a|)/\rho$$

for $\varphi \in C^{2,1}(\mathbb{R})$, $\varphi' \in L^{\infty}(\mathbb{R})$, $\varphi'' \geq 0$, $\varphi(r) = 0$ iff $r \leq c_3$. (2.3)

Exactly as above, for all $\rho \geq 0$ we let the regularized stored inelastic energy functional $\mathcal{F}_{\rho} : L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \rightarrow [0, +\infty)$ be defined as

$$\mathcal{F}_{\rho}(a) := \int_{\Omega} F_{\rho}(a)dx,$$

and $\mathcal{F}_0 := \mathcal{F}$. Finally, we shall be considering also some space-regularized situation. To this end, let $\rho, \nu \geq 0$ and define $\mathcal{F}_{\rho, \nu} : L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \rightarrow [0, +\infty]$ as

$$\mathcal{F}_{\rho, \nu}(a) := \int_{\Omega} \left(F_{\rho}(a) + \frac{\nu}{2} |\nabla a|^2 \right) dx,$$

where $(\nabla a)_{ijk} = \partial a_{ij} / \partial x_k$ is the usual gradient in the distributional sense and $|\cdot|$ denotes here the Euclidean norm.

Stored energy. Following the above introductory discussion, we define the stored (Helmholtz free) energy functional for $\rho, \nu \geq 0$ as

$$\mathcal{W}_{\rho, \nu}(u, z) := \mathcal{C}(\varepsilon(u) - z) + \mathcal{F}_{\rho, \nu}(z).$$

Load and traction. We assume to be given the body force $f \in W^{1,1}(0, T; L^2(\Omega; \mathbb{R}^3))$ and a surface traction $g \in W^{1,1}(0, T; L^2(\Gamma_{\text{tr}}; \mathbb{R}^3))$. In particular, one can define the total load $\ell \in W^{1,1}(0, T; (H^1(\Omega; \mathbb{R}^3))')$ (the prime denotes here the dual) as

$$\langle \ell(t), u \rangle := \int_{\Omega} f \cdot u dx + \int_{\Gamma_{\text{tr}}} g \cdot u d\mathcal{H}^2 \quad \forall u \in H^1(\Omega; \mathbb{R}^3), t \in [0, T],$$

where \mathcal{H}^2 is the two-dimensional Hausdorff measure and $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $(H^1(\Omega; \mathbb{R}^3))'$ and $H^1(\Omega; \mathbb{R}^3)$.

State space. We set our problem by letting

$$\mathcal{Y}^{\nu} = \mathcal{U} \times \mathcal{Z}^{\nu} := H^1(\Omega, \mathbb{R}^3) \times H^{j(\nu)}(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}).$$

Here $j(\nu) = 0$ for $\nu = 0$ and $j(\nu) = 1$ otherwise. For all $\bar{u} \in H^1(\Omega; \mathbb{R}^3)$, let us define $\mathcal{Y}^{\nu}(\bar{u}) \subset \mathcal{Y}^{\nu}$ as

$$\mathcal{Y}^{\nu}(\bar{u}) := \{(u, z) \in \mathcal{Y}^{\nu} : u = \bar{u} \text{ on } \Gamma_{\text{Dir}}\},$$

Then, for all $t \in [0, T]$, we shall define the phase space of the process as $\mathcal{Y}^{\nu}(u^{\text{Dir}}(t))$. For the sake of later purposes (see also (1.9)) let us denote by $W_{\rho} : \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3} \rightarrow [0, +\infty)$ the function

$$W_{\rho}(\varepsilon, z) := \frac{1}{2} \mathbb{C}(\varepsilon - z) : (\varepsilon - z) + F_{\rho}(z),$$

and remark that, owing to (2.2), the second derivative $\nabla^2 W_{\rho}$ is bounded and Lipschitz continuous. Moreover, we denote by $\mathcal{A}_{\nu} : \mathcal{Y}^{\nu} \rightarrow [0, \infty)$ the quadratic form

$$\mathcal{A}_{\nu}(u, z) := \mathcal{C}(\varepsilon(u) - z) + c_2 \int_{\Omega} |z|^2 dx + \frac{\nu}{2} \int_{\Omega} |\nabla z|^2 dx \quad \forall (u, z) \in \mathcal{Y}^{\nu}$$

and by $\alpha > 0$ the corresponding uniform ellipticity constant (depending on \mathbb{C} , c_2 , and ν).

Dissipation potential. The quasi-static evolution of the material is described by means of an appropriate dissipation mechanism, see (1.5). To this aim, we choose the dissipation (pseudo)-potential $D : \mathbb{R}_{\text{dev}}^{3 \times 3} \rightarrow [0, +\infty)$ to be lower semi-continuous, positively 1-homogeneous, and to fulfill the triangle inequality

$$D(a) \leq D(b) + D(c) \quad \text{whenever } a = b + c. \quad (2.4)$$

Moreover, we ask for some constant $c_D > 0$ such that

$$c_D |a| \leq D(a) \quad \forall a \in \mathbb{R}_{\text{dev}}^{3 \times 3}.$$

Under the current assumptions on D , the latter non-degeneracy condition is indeed equivalent to the fact that the set $\{a : D(a) \leq 1\}$ is bounded or that D does not

vanish except at 0. Let us stress that D turns out to be convex (see (2.4)) and that there exists a second constant $C_D > 0$ such that

$$D(a) \leq C_D |a| \quad \forall a \in \mathbb{R}_{\text{dev}}^{3 \times 3}.$$

We define the corresponding dissipation functional $\mathcal{D} : L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \rightarrow [0, +\infty)$ as

$$\mathcal{D}(a) = \int_{\Omega} D(a) dx.$$

One shall stress that indeed, since \mathcal{D} is obviously positively 1-homogeneous, a rate-independent evolution follows. Moreover, we recall here that, for all $z : [0, T] \rightarrow \mathbb{R}_{\text{dev}}^{3 \times 3}$, we let

$$\begin{aligned} & \text{Diss}_D(z, [s, t]) \\ & := \sup \left\{ \sum_{i=1}^N D(z(t_i) - z(t_{i-1})) : \{s = t_0 < t_1 < \dots < t_{N-1} < t_N = t\} \right\}, \end{aligned} \quad (2.5)$$

the supremum being chosen on the set of all finite partitions of $[s, t] \subset [0, T]$. Finally the analogous notion $\text{Diss}_{\mathcal{D}}(z, [s, t])$ will be used for functions which take values in $L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$.

State space approximation. Henceforth we will be interested in some space approximation procedure. Indeed, we assume to be given a suitable sequence of approximating closed subspaces $\mathcal{Y}_h^\nu := \mathcal{U}_h \times \mathcal{Z}_h^\nu \subset \mathcal{Y}^\nu$ depending on some parameter $h > 0$ which is intended to go to zero in the limit. We shall collect and comment here the abstract assumptions which will be exploited in the following. Of course the main application we have in mind are conforming finite elements on a shape regular and quasi-optimal mesh⁸ with size h on the polyhedral domain Ω . We will firstly ask \mathcal{Y}_h^ν to be non-decreasing and such that $\cup_{h>0} \mathcal{Y}_h^\nu$ is dense in \mathcal{Y}^ν . Moreover, we restrict from the very beginning to the special case when $\mathcal{Y}_h^0 \equiv \mathcal{Y}_h^1 \subset \mathcal{Y}^1$.

Now let $p_h^\nu : \mathcal{Y}^\nu \rightarrow \mathcal{Y}_h^\nu$ the Galerkin projector corresponding to the scalar product induced by the quadratic form \mathcal{A}_ν . In particular, by introducing the bilinear form $\mathcal{B}_\nu : \mathcal{Y}^\nu \times \mathcal{Y}^\nu \rightarrow \mathbb{R}$ defined by

$$\begin{aligned} & \mathcal{B}_\nu((u_1, z_1), (u_2, z_2)) \\ & := \frac{1}{2} \int_{\Omega} \mathbb{C}(\varepsilon(u_1) - z_1) : (\varepsilon(u_2) - z_2) + c_2 \int_{\Omega} z_1 z_2 + \frac{\nu}{2} \int_{\Omega} \nabla z_1 \cdot \nabla z_2 \end{aligned}$$

for $(u_1, z_1), (u_2, z_2) \in \mathcal{Y}^\nu$, we have that, for all $(u, z) \in \mathcal{Y}^\nu$, the projection $p_h^\nu(u, z)$ may be uniquely determined by

$$\mathcal{B}_\nu((u, z) - p_h^\nu(u, z), (u_h, z_h)) = 0 \quad \forall (u_h, z_h) \in \mathcal{Y}_h^\nu. \quad (2.6)$$

Namely, one has that

$$\mathcal{A}_\nu(p_h^\nu(u, z)) = \mathcal{B}_\nu(p_h^\nu(u, z), p_h^\nu(u, z)) \leq \mathcal{A}_\nu(u, z) \quad \forall (u, z) \in \mathcal{Y}^\nu. \quad (2.7)$$

Let us explicitly observe that p_h^ν is pointwise converging in \mathcal{Y}^ν to the identity as $h \rightarrow 0$.

Next, let us introduce a pair of operators $q_h : \mathcal{U} \rightarrow \mathcal{U}_h$ and $r_h^\nu : \mathcal{Z}^\nu \rightarrow \mathcal{Z}_h^\nu$ and ask them to be pointwise converging to the identity as $h \rightarrow 0$. More specifically, we will ask for

$$h \rightarrow 0, \quad \nu \rightarrow 0 \Rightarrow r_h^\nu(z) \rightarrow z \quad \forall z \in \mathcal{Z}^\nu.$$

Moreover, we require that

$$z \in \mathcal{Z}^0 \quad \text{and} \quad |z| \leq c_3 \quad \text{a.e. in } \Omega \Rightarrow |r_h^\nu(z)| \leq c_3 \quad \text{a.e. in } \Omega, \quad (2.8)$$

and that $r_h^0 : \mathcal{Z}^1 \rightarrow \mathcal{Z}^1$ maps bounded sets into bounded sets. As for r_h^ν an example of operator fulfilling the assumptions is the componentwise Clément interpolant from $L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$ to the space of piecewise linear functions.⁹ In this case, relation (2.8) follows from Jensen's inequality.

3. Analysis of the Constitutive Relation

Let us start our analysis by focusing on the constitutive material relation. Namely, we neglect for the moment the coupling of the material model with the equilibrium problem (1.10). Assuming to be given a tension history, we solve for the elastic and the inelastic strain starting from a given state. The understanding of this simplified (reduced) problem will be crucial. First of all, a detailed study of the constitutive relation is surely an important step in the direction of the investigation of the full quasi-static evolution problem. This is especially true with respect to numerics. Indeed, the efficient solution of the constitutive relation is the key ingredient for a full discretization procedure. Secondly, the full equilibrium system might reduce to a zero-dimensional problem under specific yet common geometric restrictions or symmetries. Finally, we aim to give in this somehow (notationally) simplified situation the main points of our analysis.

Assuming to be given $\sigma : [0, T] \rightarrow \mathbb{R}_{\text{sym}}^{3 \times 3}$, we shall determine $\varepsilon : [0, T] \rightarrow \mathbb{R}_{\text{sym}}^{3 \times 3}$ and $z : [0, T] \rightarrow \mathbb{R}_{\text{dev}}^{3 \times 3}$ starting from (ε_0, z_0) and fulfilling (1.5). Of course, since the transformation strain z is assumed to be deviatoric and the elasticity tensor \mathbb{C} decomposes as above, the problem could be easily reformulated in the deviatoric subspace $\mathbb{R}_{\text{dev}}^{3 \times 3}$ only. We however prefer not to exploit this simplification for the sake of consistency with the forthcoming analysis.

Let $\rho \geq 0$ be fixed throughout this section. We shall be concerned with the energy function $W_\rho(\varepsilon, z) - \sigma(t) : \varepsilon$ which is defined for all $(t, \varepsilon, z) \in [0, T] \times \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}$. Moreover, let us define the set of *stable states* at time $t \in [0, T]$ as

$$S(t) := \{(\varepsilon, z) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3} \text{ such that, } \forall (\bar{\varepsilon}, \bar{z}) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}, \\ W_\rho(\varepsilon, z) - \sigma(t) : \varepsilon \leq W_\rho(\bar{\varepsilon}, \bar{z}) - \sigma(t) : \bar{\varepsilon} + D(\bar{z} - z)\}, \quad (3.1)$$

and $\mathcal{S} := \cup_{t \in [0, T]} (t, S(t))$.

As for an *energetic solution* of (1.5) we mean a pair $(\varepsilon, z) : [0, T] \rightarrow \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}$ such that the function $t \mapsto \dot{\sigma}(t) : \varepsilon(t)$ is integrable and, for all $t \in [0, T]$,

$$(\varepsilon(t), z(t)) \in S(t), \tag{3.2}$$

$$\begin{aligned} W_\rho(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t) + \text{Diss}_D(z, [0, t]) \\ = W_\rho(\varepsilon_0, z_0) - \sigma(0) : \varepsilon_0 - \int_0^t \dot{\sigma}(s) : \varepsilon(s) ds. \end{aligned} \tag{3.3}$$

Let us now comment on the equivalence between (1.5) and the *energetic formulation* (3.2)–(3.3). To this end we will focus for simplicity on the smooth case $\rho > 0$. Indeed, the argument for the situation $\rho = 0$ is just slightly less straightforward from a notational viewpoint. Using the definition of the subdifferential $\partial D(\dot{z})$, relation (1.5) turns out to be equivalent to

$$\begin{aligned} (\partial_\varepsilon W_\rho(\varepsilon, z) - \sigma) : (v - \dot{\varepsilon}) + \partial_z W_\rho(\varepsilon, z) : (w - \dot{z}) + D(w) - D(\dot{z}) \geq 0 \\ \forall (v, w) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}, \quad \text{a.e. in } (0, T). \end{aligned} \tag{3.4}$$

Now, by respectively choosing $(v, w) = (k\bar{v}, k\bar{w})$ and letting $k \rightarrow +\infty$ or $(v, w) = (0, 0)$ in the latter relation we easily get that

$$\begin{aligned} (\partial_\varepsilon W_\rho(\varepsilon, z) - \sigma) : \bar{v} + \partial_z W_\rho(\varepsilon, z) : \bar{w} + D(\bar{w}) \geq 0 \\ \forall (\bar{v}, \bar{w}) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}, \quad \text{a.e. in } (0, T), \end{aligned} \tag{3.5}$$

$$(\partial_\varepsilon W_\rho(\varepsilon, z) - \sigma) : \dot{\varepsilon} + \partial_z W_\rho(\varepsilon, z) : \dot{z} + D(\dot{z}) \leq 0 \quad \text{a.e. in } (0, T). \tag{3.6}$$

Of course (3.4) and (3.5)–(3.6) are equivalent. Now, since W_ρ is strictly convex, we have that $(\varepsilon(t), z(t))$ is the almost everywhere unique minimizer of

$$(\bar{\varepsilon}, \bar{z}) \mapsto W_\rho(\bar{\varepsilon}, \bar{z}) - \sigma : \bar{\varepsilon} + D(\bar{z} - z(t)).$$

In particular, by assuming ε, z , and σ to be absolutely continuous (see below), we readily check that (3.2) holds. Moreover, (3.5) and (3.6) imply that

$$(\partial_\varepsilon W_\rho(\varepsilon, z) - \sigma) : \dot{\varepsilon} + \partial_z W_\rho(\varepsilon, z) : \dot{z} + D(\dot{z}) = 0 \quad \text{a.e. in } (0, T),$$

which can be rewritten as

$$\frac{d}{dt}(W_\rho(\varepsilon, z) - \sigma : \varepsilon) = -\dot{\sigma} : \varepsilon - D(\dot{z}) \quad \text{a.e. in } (0, T).$$

Hence, by integrating the latter on $(0, t)$ for $t \in [0, T]$, we readily deduce (3.3). Vice versa, (3.3) allows us to recover (3.5)–(3.6) at once by differentiating and exploiting (3.2).

The main advantage of the energetic formulation (3.2)–(3.3) is that it does not involve neither derivatives of constitutive quantities nor of the solution. It is hence particularly well-suited for the aim of proving well-posedness results and it simply generalizes to possibly non-convex situations.

The aim of this section is to exploit here the abstract existence theory for energetic formulations developed in Refs. 17, 28 and adapt it to the current modeling situation.

The incremental problem. In order to find an energetic solution to (3.2)–(3.3) we shall consider an implicit time discretization procedure. At first, let us observe that, for all $\bar{z} \in \mathbb{R}_{\text{dev}}^{3 \times 3}$ and $t \in [0, T]$, the function $(\varepsilon, z) \mapsto W_\rho(\varepsilon, z) - \sigma(t) : \varepsilon + D(z - \bar{z})$ has a unique minimum since it is uniformly convex and coercive. Let now the partition $P := \{0 = t_0 < t_1 < \dots < t_{N-1} < t_N = T\}$ be given with diameter $\tau = \max_{i=1, \dots, N} t_i - t_{i-1}$. Moreover, let $(\varepsilon_0, z_0) \in S(0)$ be a given initial datum. One should consider that, for any given $z_0 \in \mathbb{R}_{\text{dev}}^{3 \times 3}$, there exists a unique $\varepsilon_0 = \mathcal{L}z_0$, where $\mathcal{L} = \text{id}$ here, with $(\varepsilon_0, z_0) \in S(0)$. Hence, we solve iteratively the minimum problem

$$(\varepsilon_i, z_i) \in \underset{(\varepsilon, z) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}}{\text{Arg Min}} (W_\rho(\varepsilon, z) - \sigma(t_i) : \varepsilon + D(z - z_{i-1})) \quad \text{for } i = 1, \dots, N. \tag{3.7}$$

We shall refer to the latter as the *incremental problem* associated with (3.2)–(3.3). Let us explicitly observe that, by the triangle inequality, any solution (ε_i, z_i) to (3.7) solves also

$$(\varepsilon_i, z_i) \in \underset{(\varepsilon, z) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}}{\text{Arg Min}} (W_\rho(\varepsilon, z) - \sigma(t_i) : \varepsilon + D(z - z_i)) \quad \text{for } i = 1, \dots, N. \tag{3.8}$$

Error propagation. We shall start by providing a continuous dependence result for the single-step minimum problem in (3.7). Referring to the forthcoming time-stepping procedure, the following estimate can be seen as some error propagation control.

Lemma 3.1. (Continuous dependence) *Let $(\sigma^j, \bar{z}^j) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}$ $j = 1, 2$, be given and $(\varepsilon^j, z^j) := \text{Arg Min}_{(\varepsilon, z) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}} (W_\rho(\varepsilon, z) - \sigma^j : \varepsilon + D(z - \bar{z}^j))$. Then*

$$|\varepsilon^1 - \varepsilon^2|^2 + |z^1 - z^2|^2 \leq \frac{1}{\alpha^2} |\sigma^1 - \sigma^2|^2 + \frac{4}{\alpha} D(\bar{z}^1 - \bar{z}^2). \tag{3.9}$$

Proof. Since (ε^1, z^1) is minimal and W_ρ is uniformly convex of constant α one has that

$$\alpha |\varepsilon^1 - \varepsilon^2|^2 + \alpha |z^1 - z^2|^2 \leq W_\rho(\varepsilon^2, z^2) - \sigma^1 : \varepsilon^2 + D(z^2 - \bar{z}^1) - W_\rho(\varepsilon^1, z^1) + \sigma^1 : \varepsilon^1 - D(z^1 - \bar{z}^1).$$

On the other hand, the minimality of (ε^2, z^2) entails that

$$0 \leq W_\rho(\varepsilon^1, z^1) - \sigma^2 : \varepsilon^1 + D(z^1 - \bar{z}^2) - W_\rho(\varepsilon^2, z^2) + \sigma^2 : \varepsilon^2 - D(z^2 - \bar{z}^2).$$

Taking the sum of the latter relations and exploiting the triangle inequality (2.4) we get that

$$\alpha |\varepsilon^1 - \varepsilon^2|^2 + \alpha |z^1 - z^2|^2 \leq (\sigma^1 - \sigma^2) : (\varepsilon^1 - \varepsilon^2) + 2D(\bar{z}_1 - \bar{z}_2),$$

whence the assertion follows. □

The evolution problem. We shall now provide the main result of this section which follows by passing to the limit in the above described time-discrete approximation.

Theorem 3.1. (Existence for $\rho \geq 0$) *Given $\sigma \in W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})$ and $(\varepsilon_0, z_0) \in S(0)$ there exists an energetic solution (ε, z) to (3.2)–(3.3) such that $(\varepsilon(0), z(0)) = (\varepsilon_0, z_0)$. Moreover, $(\varepsilon, z) \in W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3})$.*

Proof. Let us choose a sequence of partitions $P^n := \{0 = t_0^n < t_1^n < \dots < t_{N^n-1}^n < t_{N^n}^n = T\}$ with diameters $\tau^n = \max_{i=1, \dots, N^n} (t_i^n - t_{i-1}^n)$ going to zero. Owing to the above discussion, we uniquely determine a sequence of solutions $\{(\varepsilon_i^n, z_i^n)\}_{i=0}^{N^n}$ to the corresponding incremental problems (3.7) such that $(\varepsilon_0^n, z_0^n) = (\varepsilon_0, z_0)$. We shall denote by (ε^n, z^n) the *incremental solution*, i.e. the right-continuous piecewise-constant interpolant of $\{(\varepsilon_i^n, z_i^n)\}_{i=0}^{N^n}$ on the partition P^n , and by $\tau^n, s^n : [0, T] \rightarrow [0, T]$ the functions $\tau^n(t) := t_i^n$ for $t \in (t_{i-1}^n, t_i^n]$, and $s^n(t) := t_{i-1}^n$ for $t \in [t_{i-1}^n, t_i^n), i = 1, \dots, N^n$.

Since $\{(\varepsilon_i^n, z_i^n)\}_{i=0}^{N^n}$ solves (3.8) with z_i^n replacing z_i , one directly gets that $(\varepsilon_i^n, z_i^n) \in S(t_i^n)$ for all $i = 1, \dots, N^n$. Moreover, from (3.7) and the minimality of (ε_i^n, z_i^n) , we compute that

$$\begin{aligned} W_\rho(\varepsilon_i^n, z_i^n) - \sigma(t_i^n) : \varepsilon_i^n - W_\rho(\varepsilon_{i-1}^n, z_{i-1}^n) + \sigma(t_{i-1}^n) : \varepsilon_{i-1}^n + D(z_i^n - z_{i-1}^n) \\ \leq -(\sigma(t_i^n) - \sigma(t_{i-1}^n)) : \varepsilon_{i-1}^n. \end{aligned}$$

Next, taking the sum of the latter relation for $i = 1, \dots, m$ and $m \leq N^n$, we get that

$$\begin{aligned} W_\rho(\varepsilon_m^n, z_m^n) - \sigma(t_m^n) : \varepsilon_m^n - W_\rho(\varepsilon_0, z_0) + \sigma(0) : \varepsilon_0 + \sum_{i=1}^m D(z_i^n - z_{i-1}^n) \\ \leq - \int_0^{t_m^n} \dot{\sigma} : \varepsilon^n ds. \end{aligned} \quad (3.10)$$

Hence, it suffices to apply the discrete Gronwall lemma and exploit the coercivity of W_ρ in order to check that

$$\sup_{t \in [0, T]} W_\rho(\varepsilon^n(t), z^n(t)) \quad \text{and} \quad \text{Diss}_D(z^n, [0, T]) \quad \text{are bounded independently of } n. \quad (3.11)$$

Indeed, the latter bound depends on $W_\rho(\varepsilon_0, z_0)$ and $\|\sigma\|_{W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})}$ only.

In order to pass to the limit with n we exploit Helly's selection principle and find a (not relabeled) subsequence of partitions and a non-decreasing function $\phi : [0, T] \rightarrow [0, +\infty)$ such that

$$z^n(t) \rightarrow z(t), \quad \text{Diss}_D(z^n, [0, t]) \rightarrow \phi(t) \quad \text{for all } t \in [0, T], \quad (3.12)$$

$$\text{and} \quad \text{Diss}_D(z, [s, t]) \leq \phi(t) - \phi(s) \quad \forall [s, t] \subset [0, T]. \quad (3.13)$$

Consequently, for all $t \in [0, T]$, we readily find the unique limit $\varepsilon(t) = \mathcal{L}z(t)$ since $\varepsilon^n(t) = \mathcal{L}z_n(t) \rightarrow \mathcal{L}z(t)$.

Next, we check that \mathcal{S} is closed. Indeed, let the sequence $(t_k, \varepsilon_k, z_k) \in \mathcal{S}$ converge to (t, ε, z) in $[0, T] \times \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}$. Then, since W_ρ is lower semicontinuous and σ is

continuous, for all $(\bar{\varepsilon}, \bar{z}) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}$,

$$\begin{aligned} W_\rho(\varepsilon, z) - \sigma(t) : \varepsilon &\leq \liminf_{k \rightarrow +\infty} (W_\rho(\varepsilon_k, z_k) - \sigma(t_k) : \varepsilon_k) \\ &\leq \liminf_{k \rightarrow +\infty} (W_\rho(\bar{\varepsilon}, \bar{z}) - \sigma(t_k) : \bar{\varepsilon} + D(\bar{z} - z_k)) \\ &= W_\rho(\bar{\varepsilon}, \bar{z}) - \sigma(t) : \bar{\varepsilon} + D(\bar{z} - z). \end{aligned}$$

Namely $(t, \varepsilon, z) \in \mathcal{S}$. We shall exploit the latter closure property in order to prove that $(\varepsilon(t), z(t))$ is a stable state. Indeed, recalling that $t \in [0, T]$ is fixed, one readily checks that the sequence $\tau^n(t)$ converges to t and is such that $(\varepsilon^n(\tau^n(t)), z^n(\tau^n(t)))$ converges to $(\varepsilon(t), z(t))$ by definition. Hence, relation (3.2) follows since $(\tau^n(t), \varepsilon^n(\tau^n(t)), z^n(\tau^n(t))) \in \mathcal{S}$. In particular, we have proved that $(\varepsilon(t), z(t))$ solves (see (3.8))

$$(\varepsilon(t), z(t)) \in \underset{(\varepsilon, z) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}}{\text{Arg Min}} (W_\rho(\varepsilon, z) - \sigma(t) : \varepsilon + D(z - z(t))).$$

Moreover, by construction, we have $(\varepsilon(0), z(0)) = (\varepsilon_0, z_0)$.

We are left to prove that indeed (ε, z) fulfills the energy identity (3.3). Relation (3.10) can be rewritten as

$$\begin{aligned} W_\rho(\varepsilon^n(t), z^n(t)) - \sigma(\tau^n(t)) : \varepsilon^n(t) + \text{Diss}_D(z^n, [0, \tau^n(t)]) \\ \leq W_\rho(\varepsilon_0, z_0) - \sigma(0) : \varepsilon_0 - \int_0^{\tau^n(t)} \dot{\sigma} : \varepsilon^n ds. \end{aligned} \tag{3.14}$$

Hence, passing to the \liminf in the latter relation and exploiting once again the lower semicontinuity of W_ρ , the integrability of $\dot{\sigma}$, the boundedness of ε^n (see (3.11)), and (3.13), we readily check by Lebesgue dominated convergence that

$$\begin{aligned} W_\rho(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t) + \text{Diss}_D(z, [0, t]) \\ \leq W_\rho(\varepsilon_0, z_0) - \sigma(0) : \varepsilon_0 - \int_0^t \dot{\sigma} : \varepsilon ds. \end{aligned} \tag{3.15}$$

Some more precise convergence for the energy can be deduced. Indeed, from the stability condition $(\varepsilon^n(t), z^n(t)) \in S(s^n(t))$, the lower semicontinuity of W_ρ , and the continuity of σ one checks that

$$\begin{aligned} W_\rho(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t) \\ = \lim_{n \rightarrow +\infty} (W_\rho(\varepsilon(t), z(t)) - \sigma(s^n(t)) : \varepsilon(t) + D(z(t) - z^n(t))) \\ \geq \limsup_{n \rightarrow +\infty} (W_\rho(\varepsilon^n(t), z^n(t)) - \sigma(s^n(t)) : \varepsilon^n(t)) \\ \geq W_\rho(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t). \end{aligned} \tag{3.16}$$

In particular, we have proved that $W_\rho(\varepsilon^n(t), z^n(t))$ converges to $W_\rho(\varepsilon(t), z(t))$.

Our next step will be that of proving that (ε, z) is absolutely continuous. Indeed this follows at once from the stability condition (3.2), the upper energy estimate (3.15), the uniform convexity of W_ρ , and the absolute continuity of σ . Let us fix

$[s, t] \subset [0, T]$. Owing to $(\varepsilon(s), z(s)) \in S(s)$ and the uniform convexity of W_ρ with constant α one readily gets that

$$\begin{aligned} & \alpha|\varepsilon(t) - \varepsilon(s)|^2 + \alpha|z(t) - z(s)|^2 \\ & \leq W_\rho(\varepsilon(t), z(t)) - \sigma(s) : \varepsilon(t) + D(z(t) - z(s)) - W_\rho(\varepsilon(s), z(s)) + \sigma(s) : \varepsilon(s) \\ & \leq W_\rho(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t) + \text{Diss}_D(z, [s, t]) \\ & \quad - W_\rho(\varepsilon(s), z(s)) + \sigma(s) : \varepsilon(s) - (\sigma(s) - \sigma(t)) : \varepsilon(t) \\ & \leq - \int_s^t \dot{\sigma}(r) : (\varepsilon(r) - \varepsilon(t)) dr. \end{aligned}$$

Hence, by means of Gronwall's lemma, one checks that

$$|\varepsilon(t) - \varepsilon(s)| + |z(t) - z(s)| \leq c_4 \int_s^t |\dot{\sigma}|, \tag{3.17}$$

where the positive constant c_4 depends just on α . The absolute continuity of ε and z follows.

We are now in the position of proving the converse inequality to (3.15), namely, the lower energy estimate. Indeed, for all $t \in [0, T]$,

$$\begin{aligned} & W_\rho(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t) + \text{Diss}_D(z, [0, t]) \\ & \geq W_\rho(\varepsilon_0, z_0) - \sigma(0) : \varepsilon_0 - \int_0^t \dot{\sigma} : \varepsilon ds. \end{aligned} \tag{3.18}$$

Indeed, let suitable partitions $Q^m = \{0 = s_0^m < s_1^m < \dots < s_{M^m-1}^m < s_{M^m}^m = t\}$ be given such that the diameters $\max_{j=1, \dots, M^m} (s_j^m - s_{j-1}^m)$ go to zero. By exploiting again the stability $(\varepsilon(s_{j-1}^m), z(s_{j-1}^m)) \in S(s_{j-1}^m)$ for $j = 1, \dots, M^m$, we obtain that

$$\begin{aligned} & W_\rho(\varepsilon(s_j^m), z(s_j^m)) - \sigma(s_j^m) : \varepsilon(s_j^m) + D(z(s_j^m) - z(s_{j-1}^m)) \\ & \geq W_\rho(\varepsilon(s_{j-1}^m), z(s_{j-1}^m)) - \sigma(s_{j-1}^m) : \varepsilon(s_{j-1}^m) - (\sigma(s_j^m) - \sigma(s_{j-1}^m)) : \varepsilon(s_j^m). \end{aligned}$$

We shall take the sum above for $j = 1, \dots, M^m$ and obtain that

$$\begin{aligned} & W_\rho(\varepsilon(t), z(t)) - \sigma(t) : \varepsilon(t) + \text{Diss}_D(z, [0, t]) \\ & \geq W_\rho(\varepsilon_0, z_0) - \sigma(0) : \varepsilon_0 - \sum_{j=1}^{M^m} (\sigma(s_j^m) - \sigma(s_{j-1}^m)) : \varepsilon(s_j^m). \end{aligned} \tag{3.19}$$

Then, relation (3.18) follows at once from Lebesgue dominated convergence since

$$- \sum_{j=1}^{M^m} (\sigma(s_j^m) - \sigma(s_{j-1}^m)) : \varepsilon(s_j^m) = - \int_0^t \left(- \int_{Q^m} \dot{\sigma} dr \right) (s) : \varepsilon(\tau^m(s)) ds,$$

where we used a standard notation for the piecewise mean on the partition Q^m . In fact, $\varepsilon \circ \tau^m$ and $-\int_{Q^m} \dot{\sigma} dr$ converge to ε and $\dot{\sigma}$ at least almost everywhere, respectively, and $\varepsilon \circ \tau^m$ is uniformly bounded. Once (3.18) is established, it is a standard matter to check that indeed $\text{Diss}_D(z, [0, t]) = \phi(t)$ for all $t \in [0, T]$. \square

Finally, a consequence of (3.17) is the following Lipschitz regularity result.

Corollary 3.1. (Lipschitz continuity) *Under the assumptions of Theorem 3.1, if $\sigma \in W^{1,\infty}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})$, then we have $(\varepsilon, z) \in W^{1,\infty}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3})$.*

We shall complement the above detailed existence analysis by providing a local Lipschitz continuous dependence result for the smooth case $\rho > 0$ (see Theorem 7.4 of Ref. 43).

Theorem 3.2. (Continuous dependence for $\rho > 0$) *Let the assumptions of Theorem 3.1 hold $\rho > 0$, $\sigma_1, \sigma_2 \in W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})$, suitably stable initial data $(\varepsilon_{0,1}, z_{0,1})$ and $(\varepsilon_{0,2}, z_{0,2})$ be given and (ε_1, z_1) and (ε_2, z_2) be two corresponding energetic solutions to (3.2)–(3.3). Then, there exists a positive constant c depending only on α , the bound and the Lipschitz constant of $\nabla^2 W_\rho$, and $\|\sigma_i\|_{W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})}$ for $i = 1, 2$ such that*

$$\begin{aligned} & |(\varepsilon_1 - \varepsilon_2)(t)|^2 + |(z_1 - z_2)(t)|^2 \\ & \leq c \left(|\varepsilon_{0,1} - \varepsilon_{0,2}|^2 + |z_{0,1} - z_{0,2}|^2 + \|\sigma_1 - \sigma_2\|_{W^{1,1}(0, t; \mathbb{R}_{\text{sym}}^{3 \times 3})}^2 \right) \quad \forall t \in [0, T]. \end{aligned} \tag{3.20}$$

Proof. Let us start by introducing some convenient notation. In particular, let

$$\begin{aligned} y_i & := \begin{pmatrix} \varepsilon_i \\ z_i \end{pmatrix}, \quad \nabla W_i := \begin{pmatrix} \partial_\varepsilon W_\rho(\varepsilon_i, z_i) \\ \partial_z W_\rho(\varepsilon_i, z_i) \end{pmatrix}, \\ \nabla^2 W_i & := \begin{pmatrix} \partial_{\varepsilon\varepsilon} W_\rho(\varepsilon_i, z_i) & \partial_{\varepsilon z} W_\rho(\varepsilon_i, z_i) \\ \partial_{\varepsilon z} W_\rho(\varepsilon_i, z_i) & \partial_{zz} W_\rho(\varepsilon_i, z_i) \end{pmatrix} \quad \text{for } i = 1, 2. \end{aligned}$$

Next, by exploiting the above-mentioned equivalence between (3.2)–(3.3) and (3.4), one readily checks that

$$(\nabla W_1 - \nabla W_2) \cdot (\dot{y}_1 - \dot{y}_2) \leq (\sigma_1 - \sigma_2) : (\dot{\varepsilon}_1 - \dot{\varepsilon}_2) \quad \text{a.e. in } (0, T), \tag{3.21}$$

where of course \cdot is the scalar product in $\mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}$. Moreover, we shall use $\bar{\varepsilon} := \varepsilon_1 - \varepsilon_2$, $\bar{z} := z_1 - z_2$ and so on. Within this proof, the symbol c will denote any positive constant possibly depending on α , $\|W_\rho\|_{C^{2,1}(\mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3})}$, and on $\|\sigma_i\|_{W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})}$ for $i = 1, 2$. Let us define

$$\gamma := \overline{\partial_\varepsilon W} : \bar{\varepsilon} + \overline{\partial_z W} : \bar{z} \geq \alpha |\bar{\varepsilon}|^2 + \alpha |\bar{z}|^2 = \alpha |\bar{y}|^2,$$

where we also used the uniform convexity of W_ρ . Now, by differentiating γ with respect to time and exploiting the smoothness of W_ρ , one gets that

$$\begin{aligned} \dot{\gamma} & = (\nabla W_1 - \nabla W_2 + \nabla^2 W_1 \bar{y}) \cdot \dot{y}_1 - (\nabla W_1 - \nabla W_2 + \nabla^2 W_2 \bar{y}) \cdot \dot{y}_2 \\ & \leq 2(\nabla W_1 - \nabla W_2) \cdot (\dot{y}_1 - \dot{y}_2) + |-\nabla W_1 + \nabla W_2 + \nabla^2 W_1 \bar{y}| |\dot{y}_1| \\ & \quad + |-\nabla W_2 + \nabla W_1 - \nabla^2 W_2 \bar{y}| |\dot{y}_2| \\ & \leq 2\bar{\sigma} : \dot{\bar{\varepsilon}} + c(|\dot{y}_1| + |\dot{y}_2|) |\bar{y}|^2 \quad \text{a.e. in } (0, T). \end{aligned}$$

By collecting the above computation we check that, for all $t \in [0, T]$,

$$\begin{aligned} \gamma(t) &= \gamma(0) + \int_0^t \gamma ds \leq \gamma(0) + 2\bar{\sigma}(t) : \bar{\varepsilon}(t) - 2\bar{\sigma}(0) : \bar{\varepsilon}_0 \\ &\quad - 2 \int_0^t \dot{\bar{\sigma}} : \bar{\varepsilon} ds + c \int_0^t (|\dot{\gamma}_1| + |\dot{\gamma}_2|) \gamma ds \\ &\leq \frac{1}{2} \gamma(t) + c \left(|\bar{\varepsilon}_0|^2 + |\bar{z}_0|^2 + |\bar{\sigma}(t)|^2 + |\sigma(0)|^2 + \int_0^t (|\dot{\gamma}_1| + |\dot{\gamma}_2|) \gamma ds \right). \end{aligned}$$

The assertion follows by Gronwall’s lemma. □

Properties of the approximations. The above detailed existence proof exploits a discrete construction which is interesting in itself. Let us condense in the following lemma the above proved results on the discrete scheme. Note that the result is less sharp for $\rho = 0$ since we do not know whether the solutions are unique in this case.

Lemma 3.2. (Convergence) *Under the assumptions of Theorem 3.1, the incremental solutions (ε^n, z^n) of problem (3.7) for partitions P^n with diameters τ^n going to zero are such that, possibly extracting a not relabeled subsequence, for all $t \in [0, T]$,*

$$\begin{aligned} z^n &\rightarrow z \quad \text{uniformly in } [0, T], \\ \text{Diss}_D(z^n, [0, t]) &\rightarrow \text{Diss}_D(z, [0, t]), \\ \varepsilon^n(t) &\rightarrow \varepsilon(t), \\ W_\rho(\varepsilon^n(t), z^n(t)) &\rightarrow W_\rho(\varepsilon(t), z(t)), \end{aligned}$$

for some pair (ε, z) which solves (3.2)–(3.3). As $\rho > 0$ the whole sequence (ε^n, z^n) converges.

We conclude this section by recalling^{43,37} an a priori error estimate of order 1/2 for the above discussed discrete approximations. The latter error bound is however restricted the smooth situation $\rho > 0$.

Lemma 3.3. (Error) *Under the assumptions of Lemma 3.2, let $\rho > 0$. Then there exists a positive constant c depending on α , the bound and the Lipschitz constant of $\nabla^2 W_\rho$, $\|W_\rho\|_{C^{2,1}(\mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3})}$, (ε_0, z_0) and $\|\sigma\|_{W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})}$ such that*

$$|(\varepsilon - \varepsilon^n)(t)| + |(z - z^n)(t)| \leq c(\tau^n)^{1/2} \quad \forall t \in [0, T]. \tag{3.22}$$

We shall not provide here a proof of the above lemma. Indeed, in case $\sigma \in W^{1,\infty}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})$ it suffices to rewrite in the current setting the argument of Theorem 4.3 of Ref. 37. Moreover, the proof can be adapted with little additional intricacy for the current absolutely continuous case $\sigma \in W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})$ as well.

4. Incremental Minimization for the Boundary Value Problem

In this section we focus on a minimum problem which arises from the time incremental approximation of the quasi-static evolution. Since we are actually dealing with a rate-independent evolution, this minimum problem is of course the basic tool for understanding the phenomenon. Moreover, the study of the time discrete seems to be heavily addressed by the engineering community.^{24,30–32,47–49} Finally, the time incremental situation will turn out to be better suited than the time-continuous one in order to prove convergence of space approximations.

The data of the minimum problem are the current value $\bar{z} \in L^2(\Omega, \mathbb{R}_{\text{dev}}^{3 \times 3})$ of the inelastic strain and the updated values $u^{\text{Dir}} \in H^1(\Omega; \mathbb{R}^3)$ of the boundary displacement and $\ell \in (H^1(\Omega; \mathbb{R}^3))'$ of the total load. We shall be interested in solving the following:

$$(u, z) \in \underset{(v, w) \in \mathcal{Y}^\nu(u^{\text{Dir}})}{\text{Arg Min}} \left(\mathcal{W}_{\rho, \nu}(v, w) - \langle \ell, v \rangle + \mathcal{D}(w - \bar{z}) \right). \quad (4.1)$$

The existence of minimizers to the latter problem is a straightforward application of the Direct Method of the Calculus of Variations.¹⁰ Indeed, $(v, w) \mapsto \mathcal{W}_{\rho, \nu}(v, w) + \mathcal{D}(w - \bar{z}) - \langle \ell, v \rangle$ is trivially coercive and lower semicontinuous with respect to the weak topology in \mathcal{Y}^ν and $\mathcal{Y}^\nu(u^{\text{Dir}})$ is convex and closed. As far as uniqueness is concerned one should observe that $\mathcal{W}_{\rho, \nu}$ is uniformly convex for all $\rho, \nu \geq 0$.

Let us state here a preliminary lemma whose proof can be obtained by means of standard computations on the quadratic form \mathcal{C} .

Lemma 4.1. (Change of boundary conditions) *Let $u^{\text{Dir}}, v^{\text{Dir}} \in H^1(\Omega; \mathbb{R}^3)$, $\bar{z} \in L^2(\Omega, \mathbb{R}_{\text{dev}}^{3 \times 3})$, and $\ell \in (H^1(\Omega; \mathbb{R}^3))'$ be given. Moreover, let $(u^*, z^*) \in \mathcal{Y}^\nu(u^{\text{Dir}})$ solve (4.1) and $v^* = u^* - u^{\text{Dir}} + v^{\text{Dir}}$. Then (v^*, z^*) solves*

$$\min_{(v, z) \in \mathcal{Y}^\nu(u^{\text{Dir}})} \left(\mathcal{W}_{\rho, \nu}(v, z) + \int_{\Omega} \mathbb{C}(\varepsilon(v) - z) : \varepsilon(u^{\text{Dir}} - v^{\text{Dir}}) - \langle \ell, v \rangle + \mathcal{D}(z - \bar{z}) \right). \quad (4.2)$$

On the other hand let (v^, z^*) solve (4.2). Then $(v^* - v^{\text{Dir}} + u^{\text{Dir}}, z^*)$ solves (4.1).*

Problem (4.1) is Hölder continuously stable with respect to perturbations on the data \bar{z}, u^{Dir} and ℓ . Indeed, we have the following generalization of Lemma 3.1.

Lemma 4.2. (Continuous dependence) *Let $\rho, \nu \geq 0$ be fixed and $\bar{z}_1, \bar{z}_2 \in L^2(\Omega, \mathbb{R}_{\text{dev}}^{3 \times 3})$, $u_1^{\text{Dir}}, u_2^{\text{Dir}} \in H^1(\Omega; \mathbb{R}^3)$ and $\ell_1, \ell_2 \in (H^1(\Omega; \mathbb{R}^3))'$ be given. Moreover, let $(u_i, z_i) \in \mathcal{Y}^\nu(u_i^{\text{Dir}})$ solve (4.1) with $u_i^{\text{Dir}} = u_i^{\text{Dir}}$, $\bar{z} = \bar{z}_i$ and $\ell = \ell_i$ for $i = 1, 2$. Then, there exists a constant c depending on c_0, α, C_D and \mathbb{C} such that*

$$\begin{aligned} & \|u_1 - u_2\|_{H^1(\Omega; \mathbb{R}^3)}^2 + \|z_1 - z_2\|_{L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 + \nu \|z_1 - z_2\|_{H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 \\ & \leq c \left(\|u_1^{\text{Dir}} - u_2^{\text{Dir}}\|_{H^1(\Omega; \mathbb{R}^3)}^2 + \|\bar{z}_1 - \bar{z}_2\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} + \|\ell_1 - \ell_2\|_{(H^1(\Omega; \mathbb{R}^3))'}^2 \right). \end{aligned} \quad (4.3)$$

Proof. We simply adapt the argument of Lemma 3.1 Owing to the minimality of (u_1, z_1) and the uniform convexity of $\mathcal{W}_{\rho,\nu}$ we readily deduce that, for any $(v_1, w_1) \in \mathcal{Y}^\nu(u_1^{\text{Dir}})$,

$$\begin{aligned} & \alpha \|\varepsilon(u_1 - v_1)\|_{L^2(\Omega; \mathbb{R}^{3 \times 3}^{\text{sym}})}^2 + \alpha \|z_1 - w_1\|_{L^2(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}})}^2 + \alpha \nu \|z_1 - w_1\|_{H^1(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}})}^2 \\ & \leq \mathcal{W}_{\rho,\nu}(v_1, w_1) - \langle \ell_1, v_1 \rangle + \mathcal{D}(w_1 - \bar{z}_1) \\ & \quad - \mathcal{W}_{\rho,\nu}(u_1, z_1) + \langle \ell_1, u_1 \rangle - \mathcal{D}(z_1 - \bar{z}_1). \end{aligned}$$

On the other hand, the minimality of (u_2, z_2) entails that, for all $(v_2, w_2) \in \mathcal{Y}^\nu(u_2^{\text{Dir}})$,

$$0 \leq \mathcal{W}_{\rho,\nu}(v_2, w_2) - \langle \ell_2, v_2 \rangle + \mathcal{D}(w_2 - \bar{z}_2) - \mathcal{W}_{\rho,\nu}(u_2, z_2) + \langle \ell_2, u_2 \rangle - \mathcal{D}(z_2 - \bar{z}_2).$$

By choosing $(v_1, w_1) = (u_2 - u_2^{\text{Dir}} + u_1^{\text{Dir}}, z_2)$ and $(v_2, w_2) = (u_1 - u_1^{\text{Dir}} + u_2^{\text{Dir}}, z_1)$ and taking the sum of the corresponding inequalities one easily deduces that

$$\begin{aligned} & \alpha \|\varepsilon(u_1 - u_2) - \varepsilon(u_1^{\text{Dir}} - u_2^{\text{Dir}})\|_{L^2(\Omega; \mathbb{R}^{3 \times 3}^{\text{sym}})}^2 \\ & \quad + \alpha \|z_1 - z_2\|_{L^2(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}})}^2 + \alpha \nu \|z_1 - z_2\|_{H^1(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}})}^2 \\ & \leq 2\mathcal{C}(\varepsilon(u_1^{\text{Dir}} - u_2^{\text{Dir}})) - \int_{\Omega} \mathbb{C}(\varepsilon(u_1 - u_2) - (z_1 - z_2)) : \varepsilon(u_1^{\text{Dir}} - u_2^{\text{Dir}}) \\ & \quad + 2\mathcal{D}(\bar{z}_1 - \bar{z}_2) + \langle \ell_1 - \ell_2, u_1 - u_2 \rangle - \langle \ell_1 - \ell_2, u_1^{\text{Dir}} - u_2^{\text{Dir}} \rangle. \end{aligned}$$

Hence, we readily find a positive constant c depending on α , C_D and \mathbb{C} in such a way that

$$\begin{aligned} & \|\varepsilon(u_1 - u_2)\|_{L^2(\Omega; \mathbb{R}^{3 \times 3}^{\text{sym}})}^2 + \|z_1 - z_2\|_{L^2(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}})}^2 + \nu \|z_1 - z_2\|_{H^1(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}})}^2 \\ & \leq c \left(\|u_1^{\text{Dir}} - u_2^{\text{Dir}}\|_{H^1(\Omega; \mathbb{R}^3)}^2 + \|\bar{z}_1 - \bar{z}_2\|_{L^1(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}})} + \|\ell_1 - \ell_2\|_{(H^1(\Omega; \mathbb{R}^3))'} \right). \end{aligned}$$

Whence, the assertion follows from Korn's inequality (2.1). \square

Convergence of space approximations. Let us now turn our attention to some space approximation procedure and recall the material of Sec. 2. We denote by $\mathcal{Y}_{h,0}^\nu$ the set $\mathcal{Y}_{h,0}^\nu := \mathcal{Y}_h^\nu \cap \mathcal{Y}^\nu(0)$. Given $(\tilde{u}, \tilde{z}) = p_h^\nu(u, z)$ we shall also denote by $p_{h,1}^\nu(u, z) := \tilde{u}$ and $p_{h,2}^\nu(u, z) := \tilde{z}$. For the sake of completeness, we shall consider also some approximate situation. Indeed, we ask that for each $(u^{\text{Dir}}, \bar{z}) \in \mathcal{Y}^\nu$ and $\ell \in (H^1(\Omega; \mathbb{R}^3))'$, there exist $(u_h^{\text{Dir}}, \bar{z}_h) \in \mathcal{Y}_h^\nu$ and $\ell_h \in (H^1(\Omega; \mathbb{R}^3))'$ such that

$$\begin{aligned} (u_h^{\text{Dir}}, \bar{z}_h) & \rightarrow (u^{\text{Dir}}, \bar{z}) \quad \text{strongly in } H^1(\Omega; \mathbb{R}^3) \times L^1(\Omega; \mathbb{R}^{3 \times 3}^{\text{dev}}), \\ & \text{and } \ell_h \rightarrow \ell \quad \text{strongly in } (H^1(\Omega; \mathbb{R}^3))'. \end{aligned} \tag{4.4}$$

We shall be concerned with the approximating minimum problem

$$(u_h, z_h) \in \underset{(u - u_h^{\text{Dir}}, z) \in \mathcal{Y}_{h,0}^\nu}{\text{Arg Min}} (\mathcal{W}_{\rho,\nu}(u, z) - \langle \ell_h, u \rangle + \mathcal{D}(z - \bar{z}_h)). \tag{4.5}$$

The latter problem is of course uniquely solvable since $(u, z) \mapsto \mathcal{W}_{\rho,\nu}(u, z) - \langle \ell_h, u \rangle + \mathcal{D}(z - \bar{z}_h)$ is again uniformly convex, coercive, and lower semicontinuous in \mathcal{Y}_h^ν and $\mathcal{Y}_{h,0}^\nu$ is convex and closed.

Assuming (4.4) and letting (u, z) and (u_h, z_h) solve the minimum problem (4.1) and (4.5), respectively, the main issue of this section is that of proving that (u_h, z_h) converges to (u, z) strongly in \mathcal{Y}^ν . More precisely, in the case $\rho > 0$, some quantitative error estimates can be obtained.

Lemma 4.3. (Error for $\rho > 0$) *Let $\rho > 0, \nu \geq 0$ be given and (u, z) and (u_h, z_h) solve (4.1) and (4.5), respectively. Moreover, let*

$$\langle \ell_h, v - p_{h,1}^\nu(v, w) \rangle = 0 \quad \text{for all } (v, w) \in \mathcal{Y}^\nu \text{ and } h > 0. \quad (4.6)$$

Then, there exists a positive constant c depending on ρ, c_0, α, C_D and \mathbb{C} such that

$$\begin{aligned} & \|u - u_h\|_{H^1(\Omega; \mathbb{R}^3)}^2 + \|z - z_h\|_{L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 + \nu \|z - z_h\|_{H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 \\ & \leq c \left(\|u^{\text{Dir}} - u_h^{\text{Dir}}\|_{H^1(\Omega; \mathbb{R}^3)}^2 + \|\bar{z} - \bar{z}_h\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} \right) \\ & \quad + c \left(\|\ell - \ell_h\|_{(H^1(\Omega; \mathbb{R}^3))'}^2 + \|z - p_{h,2}^\nu(v, z)\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} \right). \end{aligned} \quad (4.7)$$

Let us comment that (4.6) turns out to be fulfilled in the frame of conforming finite elements. Considering for simplicity the case where $p_{h,1}^\nu$ does not depend on w , a fairly usual choice for ℓ_h is

$$\langle \ell_h, v \rangle := \langle \ell, p_{h,1}^\nu(v) \rangle \quad \forall v \in \mathcal{U},$$

whence (4.6) follows.

Proof. The estimate follows by carefully reconsidering the continuous dependence proof of Lemma 4.2 and exploiting Galerkin's orthogonality (2.6). Indeed, making use of Lemma 4.1, one obtains for $v = u - u^{\text{Dir}}$ and $v_h = u_h - u_h^{\text{Dir}}$,

$$\begin{aligned} & \alpha \|\varepsilon(v - v_h)\|_{L^2(\Omega; \mathbb{R}_{\text{sym}}^{3 \times 3})}^2 + \alpha \|z - z_h\|_{L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 + \alpha \nu \|z - z_h\|_{H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 \\ & \leq \mathcal{A}_\nu(v_h, z_h) + \mathcal{G}_\rho(z_h) + \int_\Omega \mathbb{C}(\varepsilon(v_h) - z_h) : \varepsilon(u^{\text{Dir}}) + \mathcal{D}(z_h - \bar{z}) - \langle \ell, v_h - v \rangle \\ & \quad - \mathcal{A}_\nu(v, z) - \mathcal{G}_\rho(z) - \int_\Omega \mathbb{C}(\varepsilon(v) - z) : \varepsilon(u^{\text{Dir}}) - \mathcal{D}(z - \bar{z}), \end{aligned} \quad (4.8)$$

where we have denoted by $\mathcal{G}_\rho : L^2(\Omega, \mathbb{R}_{\text{dev}}^{3 \times 3}) \rightarrow [0, +\infty]$ the convex functional

$$\mathcal{G}_\rho(z) := \mathcal{F}_\rho(z) - c_2 \|z\|_{L^2(\Omega, \mathbb{R}_{\text{dev}}^{3 \times 3})}^2.$$

Moreover, arguing exactly as in Lemma 4.2 and defining $(\tilde{v}, \tilde{z}) := p_h^\nu(v, z)$, we readily check that

$$\begin{aligned} 0 & \leq \mathcal{A}_\nu(\tilde{v}, \tilde{z}) + \mathcal{G}_\rho(\tilde{z}) + \int_\Omega \mathbb{C}(\varepsilon(\tilde{v}) - \tilde{z}) : \varepsilon(u_h^{\text{Dir}}) + \mathcal{D}(\tilde{z} - \bar{z}_h) - \langle \ell_h, \tilde{v} - v_h \rangle \\ & \quad - \mathcal{A}_\nu(v_h, z_h) - \mathcal{G}_\rho(z_h) - \int_\Omega \mathbb{C}(\varepsilon(v_h) - z_h) : \varepsilon(u_h^{\text{Dir}}) - \mathcal{D}(z_h - \bar{z}_h). \end{aligned} \quad (4.9)$$

Taking the sum of the latter inequalities and exploiting (2.7), (4.6) and $(u_h^{\text{Dir}}, 0) \in \mathcal{Y}_h^\nu$, we easily check that

$$\begin{aligned} & \alpha \|\varepsilon(v - v_h)\|_{L^2(\Omega; \mathbb{R}_{\text{sym}}^{3 \times 3})}^2 + \alpha \|z - z_h\|_{L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 + \alpha \nu \|z - z_h\|_{H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 \\ & \leq \int_{\Omega} \mathbb{C}(\varepsilon(v_h - v) - (z_h - z)) : \varepsilon(u^{\text{Dir}} - u_h^{\text{Dir}}) + 2\mathcal{D}(\bar{z} - \bar{z}_h) \\ & \quad + \langle \ell - \ell_h, v - v_h \rangle + \mathcal{G}_\rho(\tilde{z}) - \mathcal{G}_\rho(z) + \mathcal{D}(z - \tilde{z}), \end{aligned}$$

and the assertion follows. \square

We shall now turn to some (necessarily weaker) quantitative convergence estimate for the specific case $\rho = 0$.

Lemma 4.4. (Convergence for $\rho = 0$) *Under the assumptions of Lemma 4.3, let $\rho = 0$. Moreover, let $(\tilde{v}, \tilde{z}) := p_h^\nu(u - u^{\text{Dir}}, z)$ and $(\hat{v}, \hat{z}) := (q_h(u - u^{\text{Dir}}), r_h^\nu(w))$. Then, there exists a positive constant c depending on c_1 and the same constant of (4.7) such that*

$$\begin{aligned} & \|u - u_h\|_{H^1(\Omega; \mathbb{R}^3)}^2 + \|z - z_h\|_{L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 + \nu \|z - z_h\|_{H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})}^2 \\ & \leq c \left(\|u^{\text{Dir}} - u_h^{\text{Dir}}\|_{H^1(\Omega; \mathbb{R}_{\text{sym}}^{3 \times 3})}^2 + \|\bar{z} - \bar{z}_h\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} + \|\ell - \ell_h\|_{(H^1(\Omega; \mathbb{R}^3))'}^2 \right) \\ & \quad + c \left(\mathcal{A}_\nu(\hat{v}, \hat{z}) - \mathcal{A}_\nu(\tilde{v}, \tilde{z}) + \int_{\Omega} \mathbb{C}(\varepsilon(\hat{v} - \tilde{v}) - (\hat{z} - \tilde{z})) : \varepsilon(u_h^{\text{Dir}}) \right) \\ & \quad + c \left(\langle \ell_h, \tilde{v} - \hat{v} \rangle + \|\hat{z} - \tilde{z}\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} + \|z - \tilde{z}\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} \right). \end{aligned} \quad (4.10)$$

Since of course $p_h(v, w) - (q_h(v), r_h^\nu(w))$ strongly converges to zero in \mathcal{Y}^ν , estimate (4.10) proves in particular that, assuming (4.4), the strong convergence of the approximations holds.

Proof. This proof follows the same lines of Lemma 4.3. We shall however replace (4.9) as follows:

$$\begin{aligned} & 0 \leq \mathcal{A}_\nu(\hat{v}, \hat{z}) + c_1 \|\hat{z}\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} + \int_{\Omega} \mathbb{C}(\varepsilon(\hat{v}) - \hat{z}) : \varepsilon(u_h^{\text{Dir}}) + \mathcal{D}(\hat{z} - \bar{z}_h) \\ & \quad - \langle \ell_h, \hat{v} - v_h \rangle - \mathcal{A}_\nu(v_h, z_h) - c_1 \|z_h\|_{L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} \\ & \quad - \int_{\Omega} \mathbb{C}(\varepsilon(v_h) - z_h) : \varepsilon(u_h^{\text{Dir}}) - \mathcal{D}(z_h - \bar{z}_h), \end{aligned}$$

and again take its sum with (4.8). In order to reduce to the situation of Lemma 4.3 one needs to simply add and subtract the term \tilde{z} in most of the occurrences of \hat{z} . This procedure of course produces the extra residual terms that appear in the last two lines of (4.10). \square

5. The Incremental Problem

We shall prepare here some material in the direction of the full time-stepping procedure. To this aim, we assume to be given a partition $P := \{0 = t_0 < t_1 < \dots < t_{N-1} < t_N = T\}$ with diameter $\tau = \max_{i=1, \dots, N}(t_i - t_{i-1})$ and data $\{u_i^{\text{Dir}}\}_{i=0}^N \in (H^1(\Omega; \mathbb{R}^3))^{N+1}$, $\{\ell_i\}_{i=0}^N \in ((H^1(\Omega; \mathbb{R}^3))')^{N+1}$, and $(u_0, z_0) \in \mathcal{Y}^\nu(u_0^{\text{Dir}})$. Hence, we find iteratively the unique solutions $\{(u_i, z_i)\}_{i=1}^N$ to the problem

$$(u_i, z_i) \in \underset{(u, z) \in \mathcal{Y}^\nu(u_i^{\text{Dir}})}{\text{Arg Min}} \left(\mathcal{W}_{\rho, \nu}(u, z) - \langle \ell_i, u \rangle + \mathcal{D}(z - z_{i-1}) \right) \quad \text{for } i = 1, \dots, N. \tag{5.1}$$

We shall denote by (u, z) the incremental solution which interpolates right-continuously the values (u_i, z_i) on the partition P . Hence, the following *a priori* estimate holds true.

Lemma 5.1. (*A priori bounds*) *Let $\rho, \nu \geq 0$. Then there exists a positive constant c depending on $\alpha, \mathcal{W}_{\rho, \nu}(u_0, z_0), \langle \ell_0, u_0 \rangle$, and $\sum_{i=1}^N \|\ell_i - \ell_{i-1}\|_{(H^1(\Omega; \mathbb{R}^3))'}$ such that*

$$\mathcal{W}_{\rho, \nu}(u, z) + \text{Diss}_{\mathcal{D}}(z, [0, T]) \leq c. \tag{5.2}$$

Proof. From the minimality of (u_i, z_i) in (5.1) one has that

$$\begin{aligned} & \mathcal{W}_{\rho, \nu}(u_i, z_i) - \langle \ell_i, u_i \rangle + \mathcal{D}(z_i - z_{i-1}) \\ & \leq \mathcal{W}_{\rho, \nu}(u_{i-1}, z_{i-1}) - \langle \ell_{i-1}, u_{i-1} \rangle - \langle \ell_i - \ell_{i-1}, u_{i-1} \rangle. \end{aligned}$$

Taking the sum in the latter relation for $i = 1, \dots, m$, $m \leq N$, one has that

$$\begin{aligned} & \mathcal{W}_{\rho, \nu}(u_m, z_m) - \langle \ell_m, u_m \rangle + \sum_{i=1}^m \mathcal{D}(z_i - z_{i-1}) \\ & \leq \mathcal{W}_{\rho, \nu}(u_0, z_0) - \langle \ell_0, u_0 \rangle - \sum_{i=1}^m \langle \ell_i - \ell_{i-1}, u_{i-1} \rangle \end{aligned}$$

and the assertion follows from the uniform convexity of $\mathcal{W}_{\rho, \nu}$ and the Gronwall lemma. □

Let us collect here some remark on the incremental problem (5.1) in the space discretized situation. To this aim we shall refer to the notation introduced in Sec. 2 and assume to be given, for all $h > 0$, suitable data $\{u_{i,h}^{\text{Dir}}\}_{i=0}^N \in (\mathcal{U}_h)^{N+1}$, $\{\ell_{i,h}\}_{i=0}^N \in ((H^1(\Omega; \mathbb{R}^3))')^{N+1}$, and $(u_{0,h}, z_{0,h})$ such that $(u_{0,h} - u_{0,h}^{\text{Dir}}, z_{0,h}) \in \mathcal{Y}_{0,h}^\nu$. Hence, by solving iteratively the minimum problem, we define the right-continuous piecewise constant incremental solutions (u_h, z_h) .

First of all, one should notice that the *a priori* bound of Lemma 5.1 holds for (u_h, z_h) as well (of course the dependences of the constant are referred to the approximating data). Secondly, we are in the position of obtaining for (u_h, z_h) the same continuous dependence as in Lemma 4.2. This fact entails the convergence of the space approximated incremental problem in N steps to the corresponding

limit. In particular, employing Lemma 4.3 or 4.4, respectively, and performing an induction over $i = 1, \dots, N$, we have the following result.

Lemma 5.2. (Convergence for N steps as $h \rightarrow 0$) *Under the above assumptions, let the parameters $\rho, \nu \geq 0$, $N \in \mathbb{N}$ be fixed and assume that $u_{i,h}^{\text{Dir}} \rightarrow u_i^{\text{Dir}}$ in $H^1(\Omega; \mathbb{R}^3)$, $\ell_{i,h} \rightarrow \ell_i$ in $(H^1(\Omega; \mathbb{R}^3))'$, and $(u_{0,h}, z_{0,h}) \rightarrow (u_0, z_0)$ in $H^1(\Omega; \mathbb{R}^3) \times L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$ as $h \rightarrow 0$. Then, we have that $u_{i,h} \rightarrow u_i$ in $H^1(\Omega; \mathbb{R}^3)$ as well, for all $i = 1, \dots, N$.*

Indeed, we would be in the position of stating a more precise quantitative bound for the error $\max_{1 \leq i \leq N} \|u_i - u_{i,h}\|_{H^1(\Omega; \mathbb{R}^3)}$ in terms of data. This bound will, however deteriorate and eventually explode as $N \rightarrow +\infty$.

6. The Evolution Problem

We shall finally turn to the study of the time-continuous problem. In particular, we are interested in *energetic solutions* to (1.5)–(1.10) along with the above prescribed boundary displacement and boundary traction conditions. Namely, our solutions will be functions $t \mapsto (u(t), z(t)) \in \mathcal{Y}^\nu(u^{\text{Dir}}(t))$ such that $t \mapsto \langle \dot{\ell}(t), u(t) \rangle$ is integrable and, for all $t \in [0, T]$,

$$(u(t), z(t)) \in \left\{ (u, z) \in \mathcal{Y}^\nu(u^{\text{Dir}}(t)) \quad \text{such that, } \forall (\bar{u}, \bar{z}) \in \mathcal{Y}^\nu(u^{\text{Dir}}(t)), \right. \\ \left. \mathcal{W}_{\rho,\nu}(u, z) - \langle \ell(t), u \rangle \leq \mathcal{W}_{\rho,\nu}(\bar{u}, \bar{z}) - \langle \ell(t), \bar{u} \rangle + \mathcal{D}(z - \bar{z}) \right\}, \tag{6.1}$$

$$\mathcal{W}_{\rho,\nu}(u(t), z(t)) - \langle \ell(t), u(t) \rangle + \text{Diss}_{\mathcal{D}}(z, [0, t]) \\ = \mathcal{W}_{\rho,\nu}(u(0), z(0)) - \langle \ell(0), u(0) \rangle - \int_0^t \langle \dot{\ell}(s), u(s) \rangle ds. \tag{6.2}$$

Following the argument of Sec. 3, we are in the position of proving the equivalence of the two formulations (1.5)–(1.10) and (6.1)–(6.2) as soon as the above-mentioned boundary condition (plus an extra homogeneous Neumann type condition for z when $\nu > 0$) are considered and the solutions are assumed to be at least absolutely continuous. The latter is of course a quite natural regularity requirement and we will readily recover it in our framework.

The main issue of this section is to fix $\nu > 0$ and exploit the analysis of Refs. 43 and 44 in order to obtain some existence, uniqueness and convergence of approximations result. Apart from infinite dimensions, the arguments involved here are quite close to those of Sec. 3. Owing to this consideration, we will mainly sketch the proofs of the forthcoming results by heavily referring to the corresponding material in Sec. 3.

An equivalent problem. It is convenient to introduce yet another equivalent formulation of problem (6.1)–(6.2) by replacing the variable u by $v = u - u^{\text{Dir}}$. The main advantage of this change of variables is that the energetic formulation for (v, z) takes values in the fixed phase space $\mathcal{Y}'_0 := \mathcal{Y}^\nu(0)$. Indeed, in the same spirit of

Lemma 4.1, one readily computes that

$$\begin{aligned} \mathcal{W}_{\rho,\nu}(u, z) - \langle \ell, u \rangle &= \mathcal{W}_{\rho,\nu}(v, z) + \int_{\Omega} \mathbb{C}(\varepsilon(v) - z) : \varepsilon(u^{\text{Dir}}) \\ &\quad - \langle \ell, v \rangle + \mathcal{C}(\varepsilon(u^{\text{Dir}})) - \langle \ell, u^{\text{Dir}} \rangle. \end{aligned}$$

Hence, one checks that (u, z) is an energetic solution if and only if $(v, z) : t \mapsto \mathcal{Y}_0^\nu$ is such that, for all $t \in [0, T]$,

$$\begin{aligned} (v(t), z(t)) \in \mathcal{S}(t) &:= \left\{ (v, z) \in \mathcal{Y}_0^\nu \quad \text{such that, } \forall (\bar{v}, \bar{z}) \in \mathcal{Y}_0^\nu, \right. \\ &\quad \left. \mathcal{W}_{\rho,\nu}(v, z) - \langle L(t), (v, z) \rangle \leq \mathcal{W}_{\rho,\nu}(\bar{v}, \bar{z}) - \langle L(t), (\bar{v}, \bar{z}) \rangle + \mathcal{D}(z - \bar{z}) \right\}, \end{aligned} \quad (6.3)$$

$$\begin{aligned} &\mathcal{W}_{\rho,\nu}(v(t), z(t)) - \langle L(t), (v(t), z(t)) \rangle + q(t) + \text{Diss}_{\mathcal{D}}(z, [0, t]) \\ &= \mathcal{W}_{\rho,\nu}(v(0), z(0)) - \langle L(0), (v(0), z(0)) \rangle + q(0) \\ &\quad - \int_0^t \langle \dot{\ell}(s), v(s) \rangle ds - \int_0^t \langle \dot{\ell}(s), u^{\text{Dir}}(s) \rangle ds, \end{aligned} \quad (6.4)$$

where we have denoted by $L : [0, T] \rightarrow (\mathcal{Y}_0^\nu)'$ the functional

$$\langle L(t), (v, z) \rangle := - \int_{\Omega} \mathbb{C}(\varepsilon(v) - z) : \varepsilon(u^{\text{Dir}}(t)) + \langle \ell(t), v \rangle \quad \forall (v, z) \in \mathcal{Y}_0^\nu, \quad t \in [0, T].$$

Here $\langle \cdot, \cdot \rangle$ is used for the duality pairing between $(\mathcal{Y}_0^\nu)'$ and \mathcal{Y}_0^ν , as well. Moreover, the function $q : [0, T] \rightarrow \mathbb{R}$ is defined as

$$q(t) := \mathcal{C}(u^{\text{Dir}}(t)) - \langle \ell(t), u^{\text{Dir}}(t) \rangle \quad \forall t \in [0, T].$$

We shall explicitly observe that $u^{\text{Dir}} \in W^{1,1}(0, T; H^1(\Omega; \mathbb{R}^3))$ and $\ell \in W^{1,1}(0, T; (H^1(\Omega, \mathbb{R}^3))')$ entail that $L \in W^{1,1}(0, T; (\mathcal{Y}_0^\nu)')$ and $q \in W^{1,1}(0, T)$.

From now on, we will focus on problem (6.3)–(6.4) and leave to the reader the straightforward interpretation of the forthcoming results for our original variable u . Let us start from the following existence result.

Theorem 6.1. (Existence for $\nu > 0$) *Let $\nu > 0$ and $\rho \geq 0$. Given $L \in W^{1,1}(0, T; (\mathcal{Y}^\nu(0))')$, $q \in W^{1,1}(0, T)$, and $(v_0, z_0) \in \mathcal{S}(0)$, there exists an energetic solution (v, z) to (6.3)–(6.4) such that $(v(0), z(0)) = (v_0, z_0)$. Moreover, $(v, z) \in W^{1,1}(0, T; \mathcal{Y}_0^\nu)$.*

We shall not provide here a full proof of this result. Indeed, it suffices to suitably adapt the machinery of Lemma 3.1 to the situation of (6.3)–(6.4). In particular, we argue again by discretizing the problem on a sequence of partitions P^n with diameter going to zero. The corresponding incremental problems

$$(v_i, z_i) \in \underset{(v, z) \in \mathcal{Y}_0^\nu}{\text{Arg Min}} \left(\mathcal{W}_{\rho,\nu}(v, z) - \langle L(t_i^n), v \rangle + \mathcal{D}(z - z_{i-1}^n) \right) \quad \text{for } i = 1, \dots, N^n, \quad (6.5)$$

will turn out to be solvable by means of the results of Sec. 4. Namely, we can introduce some right-continuous and piecewise constant interpolant (v^n, z^n) of the

discrete solution on the partition P^n . Moreover, we exploit Lemma 5.1 which entails that

$$\sup_{t \in [0, T]} \mathcal{W}_{\rho, \nu}(v^n(t), z^n(t)) \quad \text{and} \quad \text{Var}_{[0, T]}(z^n)$$
 are bounded independently of n .

Indeed, the latter bound depends now on $\mathcal{W}_{\rho, \nu}(v_0, z_0)$, $\|L\|_{W^{1,1}(0, T; (\mathcal{Y}^\nu(0)))'}$, and $\|q\|_{W^{1,1}(0, T)}$.

As for the limit, we will make use of some extended version of Helly's principle²⁸ and find a (not relabeled) subsequence of partitions and a non-decreasing function $\phi : [0, T] \rightarrow [0, +\infty)$ such that, for all $t \in [0, T]$,

$$z^n(t) \rightarrow z(t) \quad \text{weakly in } H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \quad \text{and} \quad \text{Diss}_{\mathcal{D}}(z^n, [0, t]) \rightarrow \phi(t),$$

$$\text{Diss}_{\mathcal{D}}(z, [s, t]) \leq \phi(t) - \phi(s) \quad \forall [s, t] \subset [0, T].$$

Indeed, here we have used in a crucial way that $\nu > 0$, i.e. the sublevels of $\mathcal{W}_{\rho, \nu}$ are compact in $L^2(\Omega; \mathbb{R}_{\text{sym}}^{3 \times 3}) \times L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$. Moreover, we have that $v^n(t) = \mathcal{L}z^n(t)$, \mathcal{L} being linear, and $\mathcal{L}z^n(t) \rightarrow \mathcal{L}z(t) = v(t)$ weakly in $H^1(\Omega; \mathbb{R}^3)$ for all $t \in [0, T]$, where $(v(t), 0) \in \mathcal{Y}_0^\nu$.

The set of stable trajectories $\mathcal{S} := \cup_{t \in [0, T]} (t, \mathcal{S}(t))$ is closed with respect to the weak topology of \mathcal{Y}^ν . Namely, letting $(t_k, v_k, z_k) \in \mathcal{S}$ with $t_k \rightarrow t$ and $(v_k, z_k) \rightarrow (v, z)$ weakly in \mathcal{Y}_0^ν , we readily exploit the lower semicontinuity of $\mathcal{W}_{\rho, \nu}$, the weak continuity of \mathcal{D} in $H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$, and the continuity of L and get that

$$\begin{aligned} \mathcal{W}_{\rho, \nu}(v, z) + \langle L(t), (v, z) \rangle &\leq \liminf_{k \rightarrow +\infty} (\mathcal{W}_{\rho, \nu}(v_k, z_k) + \langle L(t_k), (v_k, z_k) \rangle) \\ &\leq \liminf_{k \rightarrow +\infty} (\mathcal{W}_{\rho, \nu}(\bar{v}, \bar{z}) + \langle L(t_k), (\bar{v}, \bar{z}) \rangle + \mathcal{D}(z_k - \bar{z})) \\ &= \mathcal{W}_{\rho, \nu}(\bar{v}, \bar{z}) + \langle L(t), (\bar{v}, \bar{z}) \rangle + \mathcal{D}(z - \bar{z}) \end{aligned}$$

for all $(\bar{v}, \bar{z}) \in \mathcal{Y}_0^\nu$. Namely, $(t, v, z) \in \mathcal{S}$ and the stability condition (6.3) easily follows. Moreover, the initial condition is fulfilled by construction and the uniform convexity of $\mathcal{W}_{\rho, \nu}$ along with stability entail that the whole sequence $\varepsilon(v^n(t))$ actually converges to $\varepsilon(v(t))$.

As for proving that (v, z) fulfills (6.4) we readily deduce from the above stated convergences and lower semicontinuity arguments (see (3.14)) that the equivalent of (3.15) holds. Indeed we have that

$$\begin{aligned} &\mathcal{W}_{\rho, \nu}(v^n(t), z^n(t)) - \langle L(\tau^n(t)), (v^n(t), z^n(t)) \rangle + q(\tau^n(t)) + \text{Diss}_{\mathcal{D}}(z^n, [0, \tau^n(t)]) \\ &\leq \mathcal{W}_{\rho, \nu}(v_0, z_0) - \langle L(0), (v_0, z_0) \rangle + q(0) \\ &\quad - \int_0^{\tau^n(t)} \langle \dot{\ell}(s), v^n(s) \rangle ds - \int_0^{\tau^n(t)} \langle \dot{\ell}(s), \bar{u}(s) \rangle ds. \end{aligned} \tag{6.6}$$

and we simply pass to the \liminf as $n \rightarrow +\infty$ in order to get that

$$\begin{aligned} &\mathcal{W}_{\rho, \nu}(v(t), z(t)) - \langle L(t), (v(t), z(t)) \rangle + q(t) + \text{Diss}_{\mathcal{D}}(z, [0, t]) \\ &\leq \mathcal{W}_{\rho, \nu}(v_0, z_0) - \langle L(0), (v_0, z_0) \rangle + q(0) \\ &\quad - \int_0^t \langle \dot{\ell}(s), v(s) \rangle ds - \int_0^t \langle \dot{\ell}(s), \bar{u}(s) \rangle ds. \end{aligned} \tag{6.7}$$

Moreover, again by stability, one has that $\mathcal{W}_{\rho,\nu}(v^n(t), z^n(t)) \rightarrow \mathcal{W}_{\rho,\nu}(v(t), z(t))$ as well (see (3.16)). As a by-product, the above-stated weak convergence for $(v^n(t), z^n(t))$ turns out to be actually strong in \mathcal{Y}^ν .

Exactly as in Theorem 3.1, the absolute continuity of (v, z) follows at once from that of L and q , relation (6.7), the uniform convexity of $\mathcal{W}_{\rho,\nu}$, and stability (6.3). In particular, we are in the position of reproducing the same argument as in (3.19) and, exploiting once more stability and the continuity of data, obtain the upper energy estimate as well. Namely, one has that $\phi(t) = \text{Diss}_{\mathcal{D}}(z, [0, t])$ for all $t \in [0, T]$. The existence proof is hence complete.

Again, energetic solutions corresponding to Lipschitz continuous data turn out to be Lipschitz continuous as well.

Lemma 6.1. (Lipschitz continuity) *Under the assumptions of Theorem 6.1, whenever $L \in W^{1,\infty}(0, T; (\mathcal{Y}_0^\nu)')$ and $q \in W^{1,\infty}(0, T)$, we have $(\varepsilon, z) \in W^{1,\infty}(0, T; \mathcal{Y}_0^\nu)$.*

Existence by smoothness. The above sketched existence proof exploits in a crucial way the compactness of the sublevels of $\mathcal{W}_{\rho,\nu}$ for $\nu > 0$ in the weak topology of $H^1(\Omega; \mathbb{R}^3) \times H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$ and works for any $\rho > 0$. An alternative approach to existence of solutions of the energetic formulation is however available in the smooth situation $\rho > 0$ by means of the construction of Sec. 7 of Ref. 43, for instance. A possible advantage of this perspective is that of gaining explicit convergence rates. We shall address this issue elsewhere.

In the above-mentioned smooth situation $\rho > 0$ no compactness is assumed for energy-bounded states but the energy functional $\mathcal{W}_{\rho,\nu} : \mathcal{Y}^\nu \rightarrow [0, +\infty)$ is required to be $C^{2,1}$. This again forces $\nu > 0$. Namely, given $h \in C^{2,1}(\mathbb{R})$ with $h'' \in L^\infty(\mathbb{R})$, one has that the functional $\mathcal{H} : L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \rightarrow \mathbb{R}$ defined by

$$\mathcal{H}u := \int_{\Omega} h(u(x)) dx \quad \text{for } u \in L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$$

is $C^{2,1}$ if and only if h is quadratic (and in this case $\mathcal{H} \in C^\infty$). On the other hand, \mathcal{H} is $C^{2,1}$ on $H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$. This fact entails that $\mathcal{W}_{\rho,\nu}$ is $C^{2,1}$ on \mathcal{Y}^ν if and only if $\nu > 0$.

Continuous dependence. We are in the position of reproducing the continuous dependence result of Sec. 3 in the present framework and for $\rho, \nu > 0$. Once again continuous dependence relies on uniform convexity and $C^{2,1}$ continuity of the energy functional. In particular, the assumption $\nu > 0$, which of course plays no role in Lemma 3.2, is actually needed here (see above).

Properties of the approximations. The time discretization technique described above has of course some interest in itself. Let us collect for convenience some related result in the following.

Lemma 6.2. *Let $\nu > 0$. Under the assumptions of Theorem 6.1, the incremental solutions (v^n, z^n) of problem (6.5) for partitions P^n with diameters τ^n going to 0*

are such that, possibly extracting a not relabeled subsequence, for all $t \in [0, T]$,

$$\begin{aligned} z^n &\rightarrow z \quad \text{strongly in } C([0, T]; H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})), \\ \text{Diss}_{\mathcal{D}}(z^n, [0, t]) &\rightarrow \text{Diss}_{\mathcal{D}}(z, [0, t]), \\ v^n(t) &\rightarrow v(t) \quad \text{strongly in } H^1(\Omega; \mathbb{R}^3), \\ \mathcal{W}_{\rho, \nu}(v^n(t), z^n(t)) &\rightarrow \mathcal{W}_{\rho, \nu}(v(t), z(t)), \end{aligned}$$

for some (v, z) which solves (6.3)–(6.4). As $\rho > 0$ the whole sequence is convergent to the unique energetic solution (v, z) and there exists a positive constant c depending on α , $\|\mathcal{W}_{\rho, \nu}\|_{C^{2,1}(\mathcal{Y}_0^\nu; \mathbb{R})}$, (v_0, z_0) , $\|L\|_{W^{1,1}(0, T; (\mathcal{Y}^\nu(0))')}$, and $\|q\|_{W^{1,1}(0, T)}$ such that

$$\|(v - v^n)(t)\|_{H^1(\Omega; \mathbb{R}^3)} + \|(z - z^n)(t)\|_{H^\nu(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})} \leq c(\tau^n)^{1/2} \quad \forall t \in [0, T]. \quad (6.8)$$

Full spacetime approximations. We conclude this analysis by commenting on the possibility of performing a full spacetime approximation of the problem. To this aim let us refer to the above introduced notations, consider some approximation parameter $h > 0$, and reduce the energetic formulation (6.3)–(6.4) to the spaces $\mathcal{Y}_{h,0}^\nu$ exhausting \mathcal{Y}_0^ν . We shall be considering in particular some discrete values $\{(v_{h,i}^n, z_{h,i}^n)\}_{i=0}^{N^n}$ defined inductively from suitable initial data $(v_{h,0}, z_{h,0}) \in \mathcal{Y}_{h,0}^\nu$ by letting $(v_0^n, z_0^n) = (v_{h,0}, z_{h,0})$ and solving the following incremental problem

$$(v_{h,i}^n, z_{h,i}^n) \in \underset{(v,z) \in \mathcal{Y}_{h,0}^\nu}{\text{Arg Min}} (\mathcal{W}_{\rho, \nu}(v, z) - \langle L(t_i^n), u \rangle + \mathcal{D}(z - z_{h,i-1}^n)) \quad \text{for } i = 1, \dots, N^n. \quad (6.9)$$

Again, the unique solvability of the latter problems is ensured by uniform convexity and lower semicontinuity, i.e. it is independent of h . We will denote as usual by (v_h^n, z_h^n) the corresponding incremental solutions.

Our first observation is that, arguing exactly as above, whenever the assumptions of Theorem 6.1 are fulfilled and the initial data are bounded in energy independently of h , the usual bound

$$\begin{aligned} \sup_{t \in [0, T]} \mathcal{W}_{\rho, \nu}(v_h^n(t), z_h^n(t)) \text{ and } \text{Diss}_{\mathcal{D}}(z_h^n, [0, T]) \\ \text{are bounded indep. of } n \text{ and } h, \end{aligned} \quad (6.10)$$

can be obtained.

Convergence for the space-discretized problem. Assume $h > 0$. Then, we are in the position of reproducing the argument of Theorem 6.1 and deduce the existence of a limiting space-approximated energetic solution (v_h, z_h) . To this aim, the restriction $\nu > 0$ could even be avoided whenever \mathcal{Y}_h^ν are chosen to be finite dimensional, for instance. Moreover, the fully discrete solution (v_h^n, z_h^n) converges to (v_h, z_h) in the sense of Lemma 6.2 as $n \rightarrow +\infty$. We shall not give a detailed proof of these facts but rather limit ourselves in observing that the energetic formulation (6.3)–(6.4) can be rewritten in $\mathcal{Y}_{h,0}^\nu$ with no intricacy. In particular, estimate (6.10) is again the starting point for the limit procedure.

Once the energetic solution $(v_h, z_h) : [0, T] \rightarrow \mathcal{Y}_{h,0}^\nu$ is found (uniqueness again follows in case $\rho > 0$) we are in the condition of considering the limit as h goes to zero as well. To this aim, we shall assume that the corresponding initial data converge together with their energies, namely

$$W_{\rho,\nu}(v_{h,0}, z_{h,0}) - \langle L(0), (v_h(0), z_h(0)) \rangle \rightarrow W_{\rho,\nu}(v_0, z_0) - \langle L(0), (v_0, z_0) \rangle.$$

In this case, it is straightforward to check that the bound (6.10) is preserved while passing to the limit in h . Assuming $\nu > 0$, this entails the possibility of extracting a (not relabeled) subsequence pointwise converging to an energetic solution $(v, z) : [0, T] \rightarrow \mathcal{Y}_0^\nu$. In case $\rho > 0$, the latter is indeed the unique energetic solution whose existence is stated in Theorem 6.1. In order to check this we briefly comment on relations (6.3)-(6.4). As for (6.3), let us fix $t \in [0, T]$ and any $(\bar{v}, \bar{z}) \in \mathcal{Y}_0^\nu$ and exploit the stability of $(v_h(t), z_h(t))$ in order to get that, for all $(\bar{v}, \bar{z}) \in \mathcal{Y}^\nu$,

$$\begin{aligned} &W_{\rho,\nu}(v_h(t), z_h(t)) - \langle L(t), (v_h(t), z_h(t)) \rangle \\ &\leq W_{\rho,\nu}(p_h^\nu(\bar{v}, \bar{z})) - \langle L(t), p_h^\nu(\bar{v}, \bar{z}) \rangle + \mathcal{D}(z_h - p_{h,2}^\nu(\bar{v}, \bar{z})). \end{aligned}$$

Hence, the stability of $(v(t), z(t))$ follows by passing to the limit in h . As for the upper energy estimate we fix a uniform partition $Q^m := \{s_j^m, j = 0, \dots, M : s_j^m = jt/m\}$, exploit the upper energy estimate for (v_h, z_h) , and get that

$$\begin{aligned} &W_{\rho,\nu}(v_h(t), z_h(t)) - \langle L(t), (v_h(t), z_h(t)) \rangle + q(t) + \sum_{j=1}^m \mathcal{D}(z_h(s_j^m) - z_h(s_{j-1}^m)) \\ &\leq W_{\rho,\nu}(v_{h,0}, z_{h,0}) - \langle L(0), (v_{h,0}, z_{h,0}) \rangle + q(0) \\ &\quad - \int_0^t \langle \dot{\ell}(s), v_h(s) \rangle ds - \int_0^t \langle \dot{\ell}(s), \bar{u}(s) \rangle ds. \end{aligned}$$

It hence suffices to pass to the limit in h first and then in m in order to get the upper energy estimate for (v, z) . Finally, the lower energy estimate for (v, z) follows as above from the upper energy estimate, stability, uniform convexity of $W_{\rho,\nu}$, and the continuity of L and q . We refer to Refs. 40 and 41 for a full proof of the above convergence argument. However, we shall remark that no quantitative estimates for the approximations are given.

Convergence for the time-discretized problem. Let us consider now the limit as h goes to 0 first. Owing to Lemma 5.2 we are in the position of establishing a (quantitative) strong convergence result for the corresponding time discretized solutions (v^n, z^n) . Indeed, one could exhibit some explicit error control which however explodes with n . Moreover, in the case $\nu > 0$, since (v^n, z^n) are uniquely determined, the subsequent limit in n can be taken exactly as above and the convergence to an energetic solution (v, z) is ensured.

Joint convergence. Assume now $\nu > 0$. Owing to (6.10) we are of course in the position of passing to the limit with respect to both n and h simultaneously in (v_h^n, z_h^n) . By arguing as above the stability of the limit (v, z) will follow at once

by using the closedness of \mathcal{S} and the convergence of projections. As for the upper energy estimate, we combine the above exploited techniques and pass to the \liminf in the following relation (see (6.6))

$$\begin{aligned} & \mathcal{W}_{\rho,\nu}(v_h^n(t), z_h^n(t)) - \langle L(\tau^n(t)), (v_h^n(t), z_h^n(t)) \rangle + q(\tau^n(t)) + \text{Diss}_{\mathcal{D}}(z_h^n, [0, \tau^n(t)]) \\ & \leq \mathcal{W}_{\rho,\nu}(v_{0,h}, z_{0,h}) - \langle L(0), (v_{0,h}, z_{0,h}) \rangle + q(0) \\ & \quad - \int_0^{\tau^n(t)} \langle \dot{\ell}(s), v_h^n(s) \rangle ds - \int_0^{\tau^n(t)} \langle \dot{\ell}(s), \bar{u}(s) \rangle ds. \end{aligned} \tag{6.11}$$

Once the upper energy estimate is established, the uniform convexity of $\mathcal{W}_{\rho,\nu}$ the continuity of L and q , and the stability of (v, z) entail that also the lower energy estimate holds. Namely, (v, z) is an energetic solution to (6.3)–(6.4) and it is unique as $\rho > 0$.

Of course, whenever $\rho > 0$ we would be able to show some convergence of order $1/2$ in time. On the other hand, by passing to the limit in time we lose the chance of estimating the error in space (see above). Hence, so far we are not able to provide an explicit spacetime error bound for the joint limit procedure.

7. The Limits $\rho, \nu \rightarrow 0$

Up to this point, the parameters ρ and ν have been systematically assumed to be fixed throughout the analysis. The limit $\nu \rightarrow 0$ is however of some interest since it describes the behavior of the model toward its non-regularized limit. As for ρ we have to mention that our modeling choice corresponds to the limit situation $\rho = 0$. On the other hand, the smooth situation $\rho > 0$ is better suited for numerical implementation. Moreover, all problems are continuously dependent on data for $\rho > 0$ while energetic evolutions are not known to be unique for $\rho = 0$.

In this section we shall discuss the possibility of obtaining suitable asymptotic results for ρ and (possibly) ν going to zero within the constitutive relation, the minimum problem, the incremental problem, and the evolution problem. We will explicitly treat the space approximated case and discuss joint limits of parameters and time and/or space approximations.

As a general remark, one should notice that the choice $\rho = \nu = 0$ does not affect the well-posedness of the minimum problems since the uniform convexity of the corresponding functionals is preserved, this being true also for space approximations. Secondly, *a priori* bounds on sequences of solutions (either minimizing, incremental, or energetic) are usually available independently of the parameters. Whenever the compactness of sequences of solutions is obtained, the crucial feature in order to identify the limit of some possibly extracted subsequence is the Γ -convergence (see below) of the approximating functionals W_ρ (in the zero-dimensional case) and $\mathcal{W}_{\rho,\nu}$ (in three dimensions).

Γ -convergence issues. Let us collect here some preliminary remarks on the convergence properties of functions and functionals under consideration. The basic notion in this direction is of course that of Γ -convergence.^{18,19} The reader is referred to

Refs. 3 and 11 for a comprehensive discussion. Let us however recall here that, given a metric space X and functions $g_n, g : X \rightarrow (-\infty, +\infty]$, we say that $g_n \rightarrow g$ in the sense of Γ -convergence in X iff

$$g(x) \leq \liminf_{n \rightarrow +\infty} g_n(x_n) \quad \forall x_n \rightarrow x \quad \text{and} \tag{7.1}$$

$$\forall x \in X \quad \text{there exists } x_n \rightarrow x \quad \text{such that } g(x) \geq \limsup_{n \rightarrow +\infty} g_n(x_n). \tag{7.2}$$

We shall classically refer to (7.1) as Γ -*liminf inequality* and to x_n in (7.2) as the *recovery sequence for x* . Moreover, letting X be a Banach space, we say that $g_n \rightarrow g$ in the sense of Mosco³ if $g_n \rightarrow g$ in the sense of Γ -convergence with respect to both the strong and weak topology of X .

Let us mention that the issue of the convergence of rate-independent evolution problems under approximation is indeed a crucial one. A general abstract theory of Γ -convergence for rate-independent systems is detailed in Ref. 41.

Henceforth, we shall refer to the current choice (2.3) and explicitly ask the function f to be convex and non-decreasing. This entails in particular that $F_\rho \rightarrow F$ pointwise and non-decreasing. The smoothness of F_ρ and the latter convergence entail by means of Theorem 2.40, Ref. 3, that $F_\rho \rightarrow F$ in the sense of Γ -convergence in $\mathbb{R}_{\text{dev}}^{3 \times 3}$. As a consequence and by using Theorem 2.15, Ref. 3, we have that

$$W_\rho \rightarrow W_0 \quad \text{in the sense of } \Gamma\text{-convergence in } \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}. \tag{7.3}$$

As for the three-dimensional situation, let us start by observing that $\mathcal{F}_\rho \rightarrow \mathcal{F}$ in the sense of Γ -convergence with respect to both the strong and the weak topology in $L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$ (namely, \mathcal{F}_ρ converges to \mathcal{F}_0 in the sense of Mosco³). This fact follows at once from Theorem 2.40 of Ref. 3, and the convexity of \mathcal{F}_ρ . For all $\nu > 0$ fixed, we readily deduce in a quite similar way that $\mathcal{F}_{\rho, \nu}$ converges to $\mathcal{F}_{0, \nu}$ in the sense of Mosco in $H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$. Let us make precise the latter statement with the following.

Lemma 7.1. (Γ -convergence of the inelastic energy) *Let $\rho_k \rightarrow \rho \geq 0$ and $\nu_k \rightarrow \nu \geq 0$ be non-increasing. Then $\mathcal{F}_{\rho_k, \nu_k} \rightarrow \mathcal{F}_{\rho, \nu}$ in the sense of Mosco in $H^{j(\nu)}(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$.*

Proof. The above discussion may be readily extended in order to cover the case $\nu_k \rightarrow \nu > 0$. Let us turn to the situation $\nu = 0$ and $\nu_k > 0$ instead. Of course, the Γ -liminf inequality (7.1) easily follows from the Γ -convergence $\mathcal{F}_{\rho_k} \rightarrow \mathcal{F}_\rho$ and lower semicontinuity considerations. As for the recovery sequence, letting $z \in L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$ be fixed, we shall define z_k as the unique solution to the singular perturbation problem

$$z_k + \nu_k J z_k = z \quad \text{in } (H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}))',$$

where $J : H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \rightarrow (H^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}))'$ is the Riesz map. We have that (see, e.g. Ref. 27)

$$z_k \rightarrow z \quad \text{strongly in } L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}) \quad \text{and} \quad \frac{\nu_k}{2} \int_{\Omega} |\nabla z_k|^2 \rightarrow 0.$$

Moreover, whenever $|z| \leq c_3$ almost everywhere in Ω , the same bound holds for all z_k by the maximum principle. Hence, we readily check that

$$\mathcal{F}_{\rho_k, \nu_k}(z_k) \rightarrow \mathcal{F}_{\rho, 0}(z)$$

and the assertion follows. □

We shall now turn our attention to the convergence of stored energies and state the following.

Lemma 7.2. (Γ -convergence of the stored energy) *Let $\rho_k \rightarrow \rho \geq 0$ and $\nu_k \rightarrow \nu \geq 0$ be non-increasing. Then $\mathcal{W}_{\rho_k, \nu_k} \rightarrow \mathcal{W}_{\rho, \nu}$ in the sense of Mosco in \mathcal{Y}^ν .*

We will not provide the reader with a detailed proof. Of course, the argument can be easily reproduced by arguing along the lines of the proof of Lemma 7.1.

7.1. Constitutive relation

Let us denote by $(\varepsilon, z)_{\rho, \tau}$ the incremental solution to the constitutive relation on the partition $P := \{0 = t_0 < t_1 < \dots < t_{N-1} < t_N = T\}$ with diameter τ , namely the right-continuous piecewise constant interpolant on the time partition of the solutions $\{(\varepsilon_\rho^i, z_\rho^i)\}$ to

$$(\varepsilon_\rho^i, z_\rho^i) \in \underset{(\varepsilon, z) \in \mathbb{R}_{\text{sym}}^{3 \times 3} \times \mathbb{R}_{\text{dev}}^{3 \times 3}}{\text{Arg Min}} (W_\rho(\varepsilon, z) - \sigma(t_i) : \varepsilon + D(z - z_\rho^{i-1})) \quad i = 1, \dots, N,$$

where $\sigma \in W^{1,1}(0, T; \mathbb{R}_{\text{sym}}^{3 \times 3})$ and $(\varepsilon_\rho^0, z_\rho^0) = (\varepsilon_0, z_0)$ are given. Moreover, for all $\rho \geq 0$, we will denote by $(\varepsilon, z)_{\rho, 0}$ a solution for the time-continuous constitutive relation. Of course we would be in the position of considering approximating data $\sigma_{\rho, \tau}$ and $(\varepsilon_0, z_0)_{\rho, \tau}$ as well. We limit ourselves to the above situation just for the sake of simplicity. The main result of this subsection is the following.

Theorem 7.1. (Convergence for the constitutive relation) *Let $\rho_k \rightarrow \rho \geq 0$ and $\tau_k \rightarrow \tau \geq 0$ either being constant or converging to 0. Then, possibly up to the extraction of a subsequence in the case $(\rho, \tau) = (0, 0)$, we have that*

$$(\varepsilon, z)_{(\rho, \tau)_k} \rightarrow (\varepsilon, z)_{\rho, \tau} \quad \text{pointwise in } [0, T].$$

Indeed much more is true since the convergence of the component $z_{(\rho, \tau)_k}$ is uniform and we have convergences also of energies and dissipations. Moreover, one could consider the limits $\rho_k \rightarrow \rho > 0$ and/or $\tau_k \rightarrow \tau > 0$ as well (which we however believe to be less interesting). We limit ourselves to the above statement for the sake of clarity.

The situation of Theorem 7.1 is described in Fig. 1 below where every parameter choice (ρ, τ) in the $\rho \times \tau$ square gives rise to a solution either of the incremental problem (for $\tau > 0$) or the time-continuous problem ($\tau = 0$). Of course this solution is unique if $(\rho, \tau) \neq (0, 0)$. Theorem 7.1 entails that all the depicted limits (arrows) can be performed.

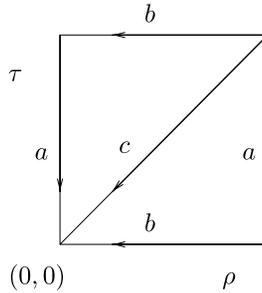

Fig. 1. Convergences for the constitutive relation.

Proof. By referring to Fig. 1, we shall proceed by discussing limits of type a , b , c and d .

Limits of type a, namely $(\rho, \tau)_k \rightarrow (\rho, 0)$. These limits follow directly from Theorem 3.1.

Limits of type b, namely $(\rho, \tau)_k \rightarrow (0, \tau)$ with $\tau > 0$. Since the time partition is fixed, the convergence of the whole sequence $(\varepsilon, z)_{(\rho_k, \tau)}$ to the corresponding incremental solution $(\varepsilon, z)_{(0, \tau)}$ is ensured by the Γ -convergence of the corresponding energy functionals, their equi-coercivity with respect to ρ , the continuity of R and the continuous dependence of the incremental problem for $\rho \geq 0$.

The limit c, namely $(\rho, \tau)_k \rightarrow (0, 0)$. Let us now turn to the joint limit. Again, the usual energy and dissipation bounds may be obtained and, by suitably choosing not relabeled subsequences, we find $(\varepsilon, z) : [0, T] \rightarrow \mathbb{R}^{3 \times 3}_{\text{sym}} \times \mathbb{R}^{3 \times 3}_{\text{dev}}$ such that $z_{(\rho, \tau)_k}(t) \rightarrow z(t)$ and $\varepsilon_{(\rho, \tau)_k}(t) \rightarrow \varepsilon(t)$ for all $t \in [0, T]$. As for proving the stability of $(\varepsilon(t), z(t))$ we simply need to specialize the closure argument in Theorem 3.1 by considering the parameter dependence on ρ . Here, the Γ -convergence (7.3) is again crucial. In particular, let us redefine (see (3.1)), for all $\rho \geq 0$,

$$S_\rho(t) := \left\{ (\varepsilon, z) \in \mathbb{R}^{3 \times 3}_{\text{sym}} \times \mathbb{R}^{3 \times 3}_{\text{dev}} \text{ such that, } \forall (\bar{\varepsilon}, \bar{z}) \in \mathbb{R}^{3 \times 3}_{\text{sym}} \times \mathbb{R}^{3 \times 3}_{\text{dev}}, \right. \\ \left. W_\rho(\varepsilon, z) - \sigma(t) : \varepsilon \leq W_\rho(\bar{\varepsilon}, \bar{z}) - \sigma(t) : \bar{\varepsilon} + D(\bar{z} - z) \right\}, \tag{7.4}$$

an $\mathcal{S}_\rho := \cup_{t \in [0, T]} (t, S_\rho(t))$. Owing to the Γ -convergence (7.3) and the continuity of σ we readily check that, for all $(t_\rho, \varepsilon_\rho, z_\rho) \in \mathcal{S}_\rho$ such that $(t_\rho, \varepsilon_\rho, z_\rho)$ converges to $(t_0, \varepsilon_0, z_0)$ as $\rho \rightarrow 0$ one has that $(t_0, \varepsilon_0, z_0) \in \mathcal{S}_0$. As for the upper energy estimate, we readily pass to the \liminf in the discrete upper equality estimate (3.14) by means of the Γ -convergence (7.3) and the fact that $W_\rho \rightarrow W_0$ pointwise. Finally, the full energy equality follows again from stability.

The limit d, namely $(\rho, 0)_k \rightarrow (0, 0)$. We shall not discuss this limit in detail since it follows easily along the lines of limit c above. □

7.2. The minimum problem

We investigate for simplicity the situation of fixed data $u^{\text{Dir}} \in H^1(\Omega; \mathbb{R}^3)$, $\ell \in (H^1(\Omega; \mathbb{R}^3))'$ and $\bar{z} \in L^2(\Omega; \mathbb{R}^{3 \times 3}_{\text{dev}})$. Of course, some more general situation of

parameter-dependent data could be considered as well (see also the forthcoming Lemma 7.4). Moreover, let us introduce for the purposes of this section the notation $\mathcal{I}_{\rho,\nu} : \mathcal{Y}^\nu \rightarrow (-\infty, +\infty]$ as

$$\mathcal{I}_{\rho,\nu}(u, z) := \mathcal{W}_{\rho,\nu}(u, z) - \langle \ell, u \rangle + \mathcal{D}(z - \bar{z}) \quad \forall (u, z) \in \mathcal{Y}^\nu,$$

for all $\rho, \nu \geq 0$. Problem (4.1) has a unique solution $(u, z)_{\rho,\nu} \in \mathcal{Y}^\nu(u^{\text{Dir}})$ for all given parameters $\rho, \nu \geq 0$. Moreover, we readily check that $\mathcal{W}_{\rho,\nu}((u, z)_{\rho,\nu})$ turns out to be bounded independently of ρ and ν . Hence, $(u, z)_{\rho,\nu}$ is weakly precompact in \mathcal{Y}^ν .

Moreover, we shall consider the space approximated situation described by the mesh-size $h > 0$. For the sake of notational simplicity, we reduce ourselves to the oversimplified situation of data independent of h . In particular, we assume $u^{\text{Dir}} \in \mathcal{U}_h$ for h small enough and define $\mathcal{Y}_h^\nu(u^{\text{Dir}}) := \mathcal{Y}_{h,0}^\nu + (u^{\text{Dir}}, 0)$. As for the general case, the following discussion has to be restricted to the situation where convergence (4.4) holds for the approximating data u_h^{Dir}, ℓ_h , and \bar{z}_h . Consequently, we will make use of the notation

$$\mathcal{I}_{\rho,\nu,h}(u, z) := \begin{cases} \mathcal{I}_{\rho,\nu}(u, z) & \text{for } (u, z) \in \mathcal{Y}_h^\nu \\ +\infty & \text{otherwise in } \mathcal{Y}^\nu. \end{cases}$$

We shall start by providing the following convergence result.

Lemma 7.3. (Γ -convergence of $\mathcal{I}_{\rho,\nu,h}$) *Let $\rho_k \rightarrow \rho \geq 0$, $\nu_k \rightarrow \nu \geq 0$, and $h > 0$. Then*

$$\mathcal{I}_{\rho_k,\nu_k} \rightarrow \mathcal{I}_{\rho,\nu} \quad \text{in the sense of Mosco in } \mathcal{Y}^\nu, \tag{7.5}$$

$$\mathcal{I}_{\rho_k,\nu_k,h} \rightarrow \mathcal{I}_{\rho,\nu,h} \quad \text{in the sense of Mosco in } \mathcal{Y}_h^\nu. \tag{7.6}$$

Moreover, let $h_k \rightarrow 0$. Then

$$\mathcal{I}_{(\rho,\nu,h)_k} \rightarrow \mathcal{I}_{\rho,\nu} \quad \text{in the sense of Mosco in } \mathcal{Y}^\nu. \tag{7.7}$$

Proof. The convergence in (7.5) follows directly from Lemma 7.2 and the strong continuity of \mathcal{D} in $L^2(\Omega, \mathbb{R}_{\text{dev}}^{3 \times 3})$.

Convergence (7.6) is also straightforward. Namely, the liminf inequality for weakly converging sequences is immediate and the construction of recovery sequences follows at once from pointwise convergence (recall that $\mathcal{Y}_h^0 = \mathcal{Y}_h^1$ hence no singular perturbation is needed here).

The full convergence situation of (7.7) deserves some comment. Given any $(u, z) \in \mathcal{Y}^\nu$, we define

$$(u, z)_{(\rho,\nu,h)_k} := (q_{h_k}(u), r_{h_k}^{\nu_k}(z)).$$

Owing to the convergence and boundedness properties of the projectors q_{h_k} and $r_{h_k}^{\nu_k}$ (see Sec. 1), we readily deduce that $(u, z)_{(\rho,\nu,h)_k} \rightarrow (u, z)$ strongly in \mathcal{Y}^ν and

$$\mathcal{W}_{(\rho,\nu,h)_k}((u, z)_{(\rho,\nu,h)_k}) \rightarrow \mathcal{W}_{\rho,\nu}(u, z).$$

The lim inf inequality follows once again from lower semicontinuity. □

The main result of this subsection concerns the possibility of considering (possibly joint) limits in the parameters ρ, ν , and h and is graphically represented in Fig. 2.

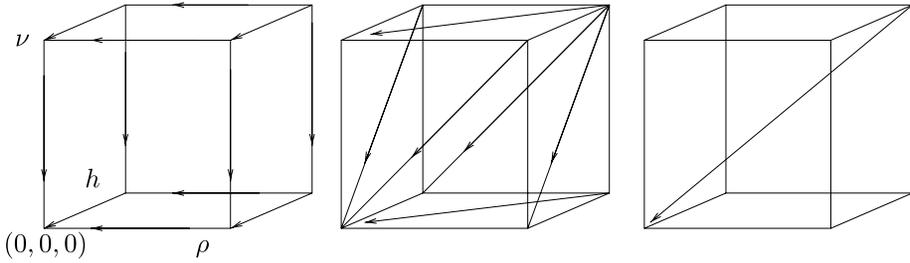

Fig. 2. Convergences for the minimum problem.

Theorem 7.2. (Convergence for the minimum problem) *Let $\rho_k \rightarrow \rho \geq 0, \nu_k \rightarrow \nu \geq 0$ and $h_k \rightarrow h \geq 0$ either being constant or converging to 0. Then*

$$(u, z)_{(\rho, \nu, h)_k} \rightarrow (u, z)_{\rho, \nu, h} \quad \text{weakly in } \mathcal{Y}^\nu \quad (\mathcal{Y}_h^\nu \text{ if } h > 0).$$

This result, whose proof is not reported, follows at once from Lemma 7.3 and the equi-coercivity and uniform convexity of the functionals. The limits $(\rho, \nu, h) \rightarrow (\rho, \nu, 0)$ were already discussed in detail in Sec. 4.

7.3. The incremental problem

We shall extend the latter asymptotics for the minimum problem to the situation of the incremental problem on the fixed partition $P := \{0 = t_0 < t_1 < \dots < t_{N-1} < t_N = T\}$. To this aim let the data $\{u^{\text{Dir}, i}\}_{i=0}^N, \{\ell^i\}_{i=0}^N$ and the initial datum (u^0, z^0) be suitably given independently of ρ and ν (for simplicity). Then, for all $\rho, \nu \geq 0$ we are entitled to solve the incremental problem and find a solution vector $\{(u_{\rho, \nu}^i, z_{\rho, \nu}^i)\}_{i=0}^N$. Now, arguing as above, we easily obtain that $\mathcal{W}_{\rho, \nu}(u_{\rho, \nu}^i, z_{\rho, \nu}^i)$ is bounded independently of ρ, ν , and i . For all given $\rho, \nu \geq 0, i = 1, \dots, N$, and $\bar{z} \in L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$, we introduce the functionals $\mathcal{J}_{\rho, \nu}^i(\cdot, \cdot, \bar{z}) : \mathcal{Y}^\nu \rightarrow (-\infty, +\infty]$ as

$$\mathcal{J}_{\rho, \nu}^i(u, z, \bar{z}) := \mathcal{W}_{\rho, \nu}(u, z) - \langle \ell^i, u \rangle + \mathcal{D}(z - \bar{z}) \quad \forall (u, z) \in \mathcal{Y}^\nu$$

Moreover, possibly taking into account the space-approximated situation, one would need to introduce space approximated data $\{u_h^{\text{Dir}, i}\}_{i=0}^N, \{\ell_h^i\}_{i=0}^N$ and the initial datum (u_h^0, z_h^0) . Let us however restrict ourselves to the (over)simplified situation where the latter can be assumed to be independent of h . For all $\rho, \nu \geq 0, h > 0, i = 1, \dots, N$, and $\bar{z} \in L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$, we shall make use of the functionals $\mathcal{J}_{\rho, \nu, h}^i(\cdot, \cdot, \bar{z}) : \mathcal{Y}^\nu \rightarrow (-\infty, +\infty]$ defined as

$$\mathcal{J}_{\rho, \nu, h}^i(u, z, \bar{z}) := \begin{cases} \mathcal{J}_{\rho, \nu}^i(u, z, \bar{z}) & \text{if } (u, z) \in \mathcal{Y}_h^\nu \\ +\infty & \text{otherwise.} \end{cases}$$

Let us start from the following Γ -convergence result.

Lemma 7.4. (Γ -convergence of $\mathcal{J}_{\rho,\nu,h}^i$) *Let $\rho_k \rightarrow \rho \geq 0$, $\nu_k \rightarrow \nu \geq 0$ and $h > 0$. Moreover, let $\bar{z}_k \rightarrow \bar{z}$ strongly in $L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$. Then, for all $i = 1, \dots, N$,*

$$\mathcal{J}_{\rho_k, \nu_k}^i(\cdot, \cdot, \bar{z}_k) \rightarrow \mathcal{J}_{\rho, \nu}^i(\cdot, \cdot, \bar{z}) \quad \text{in the sense of Mosco in } \mathcal{Y}^\nu, \quad (7.8)$$

$$\mathcal{J}_{\rho_k, \nu_k, h}^i(\cdot, \cdot, \bar{z}_k) \rightarrow \mathcal{J}_{\rho, \nu, h}^i(\cdot, \cdot, \bar{z}) \quad \text{in the sense of Mosco in } \mathcal{Y}_h^\nu. \quad (7.9)$$

Moreover, let $h_k \rightarrow 0$. Then, for all $i = 1, \dots, N$,

$$\mathcal{J}_{(\rho, \nu, h_k)}^i(\cdot, \cdot, \bar{z}_k) \rightarrow \mathcal{J}_{\rho, \nu}^i(\cdot, \cdot, \bar{z}) \quad \text{in the sense of Mosco in } \mathcal{Y}^\nu. \quad (7.10)$$

We are not reporting here the proof of the latter lemma for the sake of brevity. Indeed, the argument may be easily adapted from that of Lemma 7.3 by exploiting the strong continuity of \mathcal{D} in $L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$, its lower semicontinuity in $L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$, and the triangle inequality (2.4).

By using Lemma 7.4 and denoting by $(u, z)_{\rho, \nu}$ and $(u, z)_{\rho, \nu, h}$ the incremental solutions related to the parameter choice (ρ, ν) and, possibly, the space approximation, the main result of this subsection reads as follows.

Theorem 7.3. (Convergence for the incremental problem for $\nu > 0$) *Let $\nu > 0$ be fixed and $\rho_k \rightarrow \rho$, and $h_k \rightarrow h \geq 0$ either being constant or converging to 0. Then, for all $t \in [0, T]$,*

$$(u(t), z(t))_{\rho_k, \nu, h_k} \rightarrow (u(t), z(t))_{\rho, \nu, h} \quad \text{strongly in } \mathcal{Y}^\nu.$$

Of course, we would be in the position of considering the case $\nu_k \rightarrow \nu$, $\rho_k \rightarrow \rho > 0$ and/or $h_k \rightarrow h > 0$ as well. We however restrict to the above situation for the sake of clarity.

Lemma 7.4 entails the convergence of the incremental solutions as soon as the strong convergence of $z_{\rho_k, \nu}$ or z_{ρ_k, ν, h_k} in $L^1(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$ is ensured. In order to obtain the latter from the boundedness of energy through compactness we are forced once again to restrict our attention to the case $\nu > 0$. The proof of Theorem 7.3 follows then by simply taking steps in i .

7.4. The evolution problem

Owing to the latter discussion on the incremental problem (see Lemma 7.4), we shall restrict ourselves to the situation $\nu > 0$ from the very beginning (note that the existence is not known for $\nu = 0$). For all $\rho, h \geq 0$, let us denote by $(v, z)_\rho : [0, T] \rightarrow \mathcal{Y}_\rho^\nu$ and $(v, z)_{\rho, h} : [0, T] \rightarrow \mathcal{Y}_{0, h}^\nu$ the solutions to the corresponding energetic formulations for $h = 0$ and $h > 0$ (here and in what follows we have assumed the data L, q and the initial datum (v^0, z^0) to be fixed independently of all approximations). The latter solutions are known to exist and turn out to be unique for $\rho > 0$. Moreover, let $(v, z)_{\rho, \tau}$ and $(v, z)_{\rho, \tau, h}$ denote the unique incremental solutions to the problem on a given partition with diameter τ .

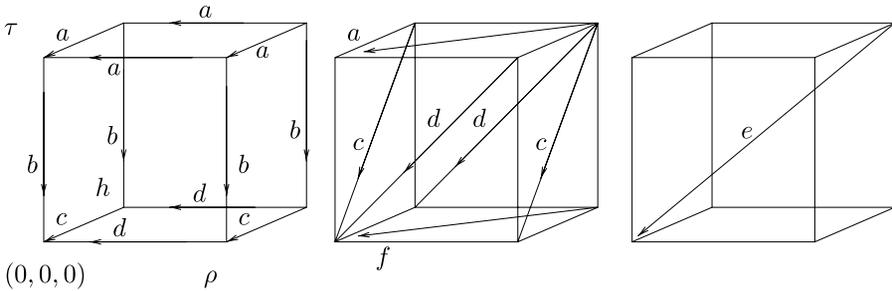

Fig. 3. Convergences for the evolution problem ($\nu > 0$).

A variety of convergence results for $(v, z)_\rho$, $(v, z)_{\rho,h}$, $(v, z)_{\rho,\tau}$, and $(v, z)_{\rho,\tau,h}$ have already been obtained. This subsection will complement the above discussions and complete the picture of convergence results for the time-continuous evolution problem. In particular, as soon as $\nu > 0$ is fixed, we are entitled to take (possibly joint) limits in (ρ, τ, h) as it is graphically depicted in Fig. 3.

The main result of this subsection reads as follows.

Theorem 7.4. (Convergence for the evolution problem for $\nu > 0$) *Let $\nu > 0$ be fixed and $\rho_k \rightarrow \rho$, $\tau_k \rightarrow \tau \geq 0$, and $h_k \rightarrow h \geq 0$ either being constant or converging to 0. Then, possibly extracting not-relabeled subsequences if $(\rho, \tau) = (0, 0)$, for all $t \in [0, T]$,*

$$(v(t), z(t))_{(\rho,\tau,h)_k} \rightarrow (v(t), z(t))_{\rho,\tau,h} \quad \text{strongly in } \mathcal{Y}_0^\nu.$$

Proof. (Sketch of the proof) Referring to Fig. 3, let us start by observing that the limits of type *a* and *b* were already obtained in Theorems 7.3 and 6.1, respectively. Moreover, the limits of type *c* have been discussed at the end of Sec. 6.

Limits of type d. This limit can be established by simply adapting to the current three-dimensional situation the argument of Theorem 7.1. In case $h > 0$, the latter adaptation is even simplified by finite-dimensionality and the convergence result would hold for $\nu = 0$ as well.

The limit e. By suitably extracting (not-relabeled) subsequences we readily find $(v, z) : [0, T] \rightarrow \mathcal{Y}_0^\nu$ such that, for all $t \in [0, T]$,

$$\begin{aligned} (v(t), z(t))_{(\rho,\tau,h)_k} &\rightarrow (v(t), z(t)) && \text{weakly in } \mathcal{Y}_0^\nu, \\ z_{(\rho,\tau,h)_k}(t) &\rightarrow z(t) && \text{strongly in } L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3}). \end{aligned} \tag{7.11}$$

Hence, we are left to prove that indeed (v, z) is a solution of the evolution problem, i.e. check for the stability condition (6.1) and the energy equality (6.2).

As for the former, we exploit Lemma 7.2 and, for all $(\bar{v}, \bar{z}) \in \mathcal{Y}_0^\nu$, by letting $(\bar{v}, \bar{z})_k := (q_{h_k}(\bar{v}), r_{h_k}^\nu(\bar{z}))$ we check that

$$\begin{aligned} &\mathcal{W}_{0,\nu}(v(t), z(t)) - \langle L(t), (v(t), z(t)) \rangle \\ &\leq \liminf_{k \rightarrow +\infty} \left(\mathcal{W}_{\rho_k,\nu}((v(t_{\tau_k}), z(t_{\tau_k}))_{(\rho,\tau,h)_k}) - \langle L(t_{\tau_k}), ((v(t_{\tau_k}), z(t_{\tau_k}))_{(\rho,\tau,h)_k}) \rangle \right) \end{aligned}$$

$$\begin{aligned} &\leq \liminf_{k \rightarrow +\infty} \left(\mathcal{W}_{\rho_k, \nu}((\bar{v}, \bar{z})_k) - \langle L(t_{\tau_k}), ((\bar{v}, \bar{z})_k) + \mathcal{D}(\bar{z}_h - z_{(\rho, \tau, h)_k}) \right) \\ &= \mathcal{W}_{0, \nu}(\bar{v}, \bar{z}) - \langle L(t), (\bar{v}, \bar{z}) \rangle + \mathcal{D}(\bar{z} - z(t)), \end{aligned}$$

where we used some obvious notation for the point t_{τ_k} on the time-partition of diameter τ_k such that $0 \leq t - t_{\tau_k} < \tau_k$, Lemma 7.2, the stability of $(v, z)_{(\rho, \tau, h)_k}$ at time t_{τ_k} , and the strong continuity of \mathcal{D} in $L^2(\Omega; \mathbb{R}_{\text{dev}}^{3 \times 3})$.

The upper energy estimate (and hence (6.2)) follows by simply passing to the \liminf as $(\rho, \tau, h)_k \rightarrow (0, 0, 0)$ in the discrete upper energy estimate (6.6).

The limit f. This limit can be obtained along the same lines of limit e above, the argument being even simplified by the fact that here $\tau_k = 0$ and the upper energy estimate follows by passing to the \liminf as $(\rho, h)_k \rightarrow (0, 0)$ in the time-continuous upper energy estimate (6.7). \square
